Nushell Team

# Chapter 1

## Introduction

Hello, and welcome to the Nushell project. The goal of this project is to take the Unix philosophy of shells, where pipes connect simple commands together, and bring it to the modern style of development.

Nu takes cues from a lot of familiar territory: traditional shells like bash, object based shells like PowerShell, gradually typed languages like TypeScript, functional programming, systems programming, and more. But rather than trying to be a jack of all trades, Nu focuses its energy on doing a few things well:

- Being a flexible cross-platform shell with a modern feel
- Solving problems as a modern programming language that works with the structure of your data
- Giving clear error messages and clean IDE support

The easiest way to see what Nu can do is to start with some examples, so let's dive in.

The first thing you'll notice when you run a command like `ls` is that instead of a block of text coming back, you get a structured table.

```
> ls
```

#	name	type	size	modified
0	404.html	file	429 B	3 days ago

```

1  CONTRIBUTING.md      file      955 B   8 mins
ago
2  Gemfile              file      1.1 KiB  3 days
ago
3  Gemfile.lock         file      6.9 KiB  3 days
ago
4  LICENSE              file      1.1 KiB  3 days
ago
5  README.md           file       213 B   3 days
ago
...
```

The table is more than just showing the directory in a different way. Just like tables in a spreadsheet, this table allows us to work with the data more interactively.

The first thing we'll do is to sort our table by size. To do this, we'll take the output from `ls` and feed it into a command that can sort tables based on the contents of a column.

```

> ls | sort-by size | reverse

#           name           type      size      modified

0  Gemfile.lock           file      6.9 KiB   3 days
ago
1  SUMMARY.md             file      3.7 KiB   3 days
ago
2  Gemfile                file      1.1 KiB   3 days
ago
3  LICENSE                file      1.1 KiB   3 days
ago
4  CONTRIBUTING.md        file       955 B    9 mins
ago
5  books.md               file       687 B    3 days
ago
...
```

You can see that to make this work we didn't pass commandline arguments to `ls`. Instead, we used the `sort-by` command that Nu provides

to do the sorting of the output of the `ls` command. To see the biggest files on top, we also used `reverse`.

Nu provides many commands that can work on tables. For example, we could filter the contents of the `ls` table so that it only shows files over 1 kilobyte:

```
> ls | where size > 1kb
```

#	name	type	size	modified
0	Gemfile	file	1.1 KiB	3 days ago
1	Gemfile.lock	file	6.9 KiB	3 days ago
2	LICENSE	file	1.1 KiB	3 days ago
3	SUMMARY.md	file	3.7 KiB	3 days ago

Just as in the Unix philosophy, being able to have commands talk to each other gives us ways to mix-and-match in many different combinations. Let's look at a different command:

```
> ps
```

#	pid	name	status	cpu
mem	virtual			
0	7570	nu	Running	1.96 23.
2 MiB	32.8 GiB			
1	3533	remindd	Sleep	0.00 103.
6 MiB	32.3 GiB			
2	3495	TVCacheExtension	Sleep	0.00 11.
9 MiB	32.2 GiB			
3	3490	MusicCacheExtension	Sleep	0.00 12.
9 MiB	32.2 GiB			
...				

You may be familiar with the `ps` command if you've used Linux. With it, we can get a list of all the current processes that the system is running, what their status is, and what their name is. We can also see the CPU load for the processes.

What if we wanted to show the processes that were actively using the CPU? Just like we did with the `ls` command earlier, we can also work with the table that the `ps` command gives back to us:

---

```
> ps | where cpu > 5
```

```

#  pid      name      status  cpu      mem
  virtual
0  1583  Terminal      Running  20.69  127.8 MiB
33.0 GiB
1   579  photoanalysisd Running  139.50   99.9 MiB
32.3 GiB

```

So far, we've been using **ls** and **ps** to list files and processes. Nu also offers other commands that can create tables of useful information. Next, let's explore **date** and **sys**.

Running **date now** gives us information about the current day and time:

```
> date now
2022-03-07 14:14:51.684619600 -08:00
```

To get the date as a table we can feed it into **date to-table**

```
> date now | date to-table
```

#	year	month	day	hour	minute	second	timezone
0	2022	3	7	14	45	3	-08:00

Running **sys** gives information about the system that Nu is running on:

```
> sys
```

host	{record 6 fields}
cpu	[table 4 rows]
disks	[table 3 rows]
mem	{record 4 fields}
temp	[table 1 row]

```
net      [table 4 rows]
```

This is a bit different than the tables we saw before. The `sys` command gives us a table that contains structured tables in the cells instead of simple values. To take a look at this data, we need to *get* the column to view:

```
> sys | get host

name          Debian GNU/Linux
os version    11
kernel version 5.10.92-v8+
hostname      lifeless
uptime        19day 21hr 34min 45sec
sessions      [table 1 row]
```

The `get` command lets us jump into the contents of a column of the table. Here, we’re looking into the “host” column, which contains information about the host that Nu is running on. The name of the OS, the hostname, the CPU, and more. Let’s get the name of the users on the system:

```
> sys | get host.sessions.name

0   jt
```

Right now, there’s just one user on the system named “jt”. You’ll notice that we can pass a column path (the `host.sessions.name` part) and not just the name of the column. Nu will take the column path and go to the corresponding bit of data in the table.

You might have noticed something else that’s different. Rather than having a table of data, we have just a single element: the string “jt”. Nu works with both tables of data as well as strings. Strings are an important part of working with commands outside of Nu.

Let’s see how strings work outside of Nu in action. We’ll take our example from before and run the external `echo` command (the `^` tells Nu to not use the built-in `echo` command):

```
> sys | get host.sessions.name | each { |it| ^echo $it
}
jt
```

If this looks very similar to what we had before, you have a keen eye! It is similar, but with one important difference: we've called `^echo` with the value we saw earlier. This allows us to pass data out of Nu into `echo` (or any command outside of Nu, like `git` for example).

## Getting Help

Help text for any of Nu's builtin commands can be discovered with the `help` command. To see all commands, run `help commands`. You can also search for a topic by doing `help -f <topic>`.

```
> help path
Explore and manipulate paths.
```

There are three ways to represent a path:

- \* As a path literal, e.g., `"/home/viking/spam.txt"`
- \* As a structured path: a table with `'parent'`, `'stem'`, and `'extension'` (and `'prefix'` on Windows) columns. This format is produced by the `'path parse'` subcommand.
- \* As an inner list of path parts, e.g., `'[[ / home viking spam.txt ]]'`.  
Splitting into parts is done by the `'path split'` command.

All subcommands accept all three variants as an input. Furthermore, the `'path join'` subcommand can be used to join the structured path or path parts back into the path literal.

Usage:

```
> path
```

**Subcommands:**

- path basename - Get the final component of a path
- path dirname - Get the parent directory of a path
- path exists - Check whether a path exists
- path expand - Try to expand a path to its absolute form
- path join - Join a structured path or a list of path parts.
- path parse - Convert a path into structured data.
- path relative-to - Get a path as relative to another path.
- path split - Split a path into parts by a separator.
- path type - Get the type of the object a path refers to (e.g., file, dir, symlink)

**Flags:**

- h, --help  
Display this help message

# Chapter 2

## Installing Nu

There are lots of ways to get Nu up and running. You can download pre-built binaries from our [release page](#)<sup>1</sup>, [use your favourite package manager](#)<sup>2</sup>, or build from source.

### Pre-built binaries

Nu binaries are published for Linux, macOS, and Windows [with each GitHub release](#)<sup>3</sup>. Just download, extract the binaries, then copy them to a location on your PATH.

### Package managers

Nu is available via several package managers:

<sup>4</sup>For macOS and Linux, [Homebrew](#)<sup>5</sup> is a popular choice (`brew install nushell`).

For Windows:

- [Winget](#)<sup>6</sup> (`winget install nushell`)
- [Chocolatey](#)<sup>7</sup> (`choco install nushell`)

---

<sup>1</sup><https://github.com/nushell/nushell/releases>

<sup>2</sup><https://repology.org/project/nushell/versions>

<sup>3</sup><https://github.com/nushell/nushell/releases>

<sup>4</sup><https://repology.org/project/nushell/versions>

<sup>5</sup><https://brew.sh/>

<sup>6</sup><https://docs.microsoft.com/en-us/windows/package-manager/winget/>

<sup>7</sup><https://chocolatey.org/>

- [Scoop](#)<sup>8</sup> (`scoop install nu`)

## Build from source

You can also build Nu from source. First, you will need to set up the Rust toolchain and its dependencies.

## Installing a compiler suite

For Rust to work properly, you'll need to have a compatible compiler suite installed on your system. These are the recommended compiler suites:

- Linux: GCC or Clang
- macOS: Clang (install Xcode)
- Windows: MSVC (install [Visual Studio](#)<sup>9</sup> or the [Visual Studio Build Tools](#)<sup>10</sup>)
  - Make sure to install the “Desktop development with C++” workload
  - Any Visual Studio edition will work (Community is free)

## Installing Rust

If we don't already have Rust on our system, the best way to install it is via [rustup](#)<sup>11</sup>. Rustup is a way of managing Rust installations, including managing using different Rust versions.

Nu currently requires the **latest stable (1.59 or later)** version of Rust. The best way is to let [rustup](#) find the correct version for you. When you first open [rustup](#) it will ask what version of Rust you wish to install:

```
Current installation options:
```

```
default host triple: x86_64-unknown-linux-gnu
default toolchain: stable
```

---

<sup>8</sup><https://scoop.sh/>

<sup>9</sup><https://visualstudio.microsoft.com/vs/community/>

<sup>10</sup><https://visualstudio.microsoft.com/downloads/#build-tools-for-visual-studio-2022>

<sup>11</sup><https://rustup.rs/>

```
profile: default
modify PATH variable: yes

1) Proceed with installation (default)
2) Customize installation
3) Cancel installation
```

Once we are ready, we press 1 and then enter.

If you'd rather not install Rust via **rustup**, you can also install it via other methods (e.g. from a package in a Linux distro). Just be sure to install a version of Rust that is 1.59 or later.

## Dependencies

### Debian/Ubuntu

You will need to install the “pkg-config” and “libssl-dev” package:

```
apt install pkg-config libssl-dev
```

Linux users who wish to use the **rawkey** or **clipboard** optional features will need to install the “libx11-dev” and “libxcb-composite0-dev” packages:

```
apt install libxcb-composite0-dev libx11-dev
```

### RHEL based distros

You will need to install “libxcb”, “openssl-devel” and “libX11-devel”:

```
yum install libxcb openssl-devel libX11-devel
```

### macOS

Using **Homebrew**<sup>12</sup>, you will need to install “openssl” and “cmake” using:

---

<sup>12</sup><https://brew.sh/>

```
brew install openssl cmake
```

## Build using [crates.io](https://crates.io)<sup>13</sup>

Nu releases are published as source to the popular Rust package registry [crates.io](https://crates.io)<sup>14</sup>. This makes it easy to build+install the latest Nu release with `cargo`:

```
> cargo install nu
```

That's it! The `cargo` tool will do the work of downloading Nu and its source dependencies, building it, and installing it into the cargo bin path so we can run it.

If you want to install with more features, you can use:

```
> cargo install nu --features=extra
```

Once installed, we can run Nu using the `nu` command:

```
$ nu  
/home/jt/Source>
```

## Building from the GitHub repository

We can also build our own Nu from the latest source on GitHub. This gives us immediate access to the latest features and bug fixes. First, clone the repo:

```
> git clone https://github.com/nushell/nushell.git
```

From there, we can build and run Nu with:

```
> cd nushell  
nushell> cargo build --workspace --features=extra && cargo  
run --features=extra
```

You can also build and run Nu in release mode:

---

<sup>13</sup><https://crates.io>

<sup>14</sup><https://crates.io/>

```
nushell> cargo build --release --workspace --features=extra
&& cargo run --release --features=extra
```

People familiar with Rust may wonder why we do both a “build” and a “run” step if “run” does a build by default. This is to get around a shortcoming of the new `default-run` option in Cargo, and ensure that all plugins are built, though this may not be required in the future.

## Setting the login shell (\*nix)

**!!! Nu is still in development, and may not be stable for everyday use. !!!**

To set the login shell you can use the `chsh`<sup>15</sup> command. Some Linux distributions have a list of valid shells located in `/etc/shells` and will disallow changing the shell until Nu is in the whitelist. You may see an error similar to the one below if you haven’t updated the `shells` file:

```
chsh: /home/username/.cargo/bin/nu is an invalid shell
```

You can add Nu to the list of allowed shells by appending your Nu binary to the `shells` file. The path to add can be found with the command `which nu`, usually it is `$HOME/.cargo/bin/nu`.

## Setting the default shell (Windows Terminal)

If you are using **Windows Terminal**<sup>16</sup> you can set `nu` as your default shell by adding:

```
{
  "guid": "{2b372ca1-1ee2-403d-a839-6d63077ad871}",
  "hidden": false,
  "name": "Nu Shell",
  "commandline": "nu.exe"
}
```

---

<sup>15</sup><https://linux.die.net/man/1/chsh>

<sup>16</sup><https://github.com/microsoft/terminal>

to "profiles" in your Terminal Settings (JSON-file). The last thing to do is to change the "defaultProfile" to:

```
"defaultProfile": "{2b372ca1-1ee2-403d-a839-6d63077ad871}",
```

Now, nu should load on startup of the Windows Terminal.

## Chapter 3

# Thinking in Nu

To help you understand - and get the most out of - Nushell, we've put together this section on "thinking in Nushell". By learning to think in Nushell and use the patterns it provides, you'll hit fewer issues getting started and be better setup for success.

So what does it mean to think in Nushell? Here are some common topics that come up with new users of Nushell.

### Nushell isn't bash

Nushell is both a programming language and a shell and because of this has its own way of working with files, directories, websites, and more. We've modeled this to work closely with what you may be familiar with other shells. Pipelines work by attaching two commands together:

```
> ls | length
```

Nushell, for example, also has support for other common capabilities like getting the exit code from previously run commands.

While it does have these amenities, Nushell isn't bash. The bash way of working, and the POSIX style in general, is not one that Nushell supports. For example, in bash, you might use:

```
> echo "hello" > output.txt
```

In Nushell, we use the `>` as the greater-than operator. This fits better with the language aspect of Nushell. Instead, you pipe to a command that has the job of saving content:

```
> echo "hello" | save output.txt
```

**Thinking in Nushell:** The way Nushell views data is that data flows through the pipeline until it reaches the user or is handled by a final command. Nushell uses commands to do work. Learning these commands and when to use them helps you compose many kinds of pipelines.

## Parsing and evaluation are different stages

An important part of Nushell's design and specifically where it differs from many dynamic languages is that “parse time” and “evaluation time” are separate and do not mix. These terms come from programming language design and compiler theory, in which parsing is where you convert text to an abstract representation, and evaluation is where you run the abstract representation.

For example, the following doesn't make sense in Nushell, and will fail to execute if run as a script:

```
echo "def abc [] { 1 + 2 }" | save output.nu
source "output.nu"
abc
```

The `source` command runs at parse time, where the parser finds all the definitions that are visible to the program. By evaluation time, those definitions should all be visible. However, since the `output.nu` file is not created until evaluation time (by the `save` command), the `source` command is unable to read definitions from it during parse time.

In the above, we've expected the evaluator to run between each line, but Nushell does not interleave parsing and evaluation like this.

Another common issue is trying to dynamically create the filename to source from:

```
> source "$($my-path)/common.nu"
```

This would require the evaluator to run and evaluate the string before the parser was able to look inside the file to find definitions. Again, this mixes parsing and evaluation, no longer keeping them separate.

**Thinking in Nushell:** Nushell is designed to use a single parsing phase separate from evaluation. This will allow for strong IDE support, accurate error messages, and an easier language for third-party tools to work with.

## Variables are immutable

Another common surprise for folks coming from other languages is that Nushell variables are immutable (and indeed some people have started to call them “constants” to reflect this). Coming to Nushell you’ll want to spend some time becoming familiar with working in a more functional style, as this tends to help write code that works best with immutable variables.

You might wonder why Nushell uses immutable variables. Early on in Nushell’s development we decided to see how long we could go using a more data-focused, functional style in the language. More recently, we added a key bit of functionality into Nushell that made these early experiments show their value: parallelism. By switching from **each** to **par-each** in any Nushell script, you’re able to run the corresponding block of code in parallel over the input. This is possible because Nushell’s design leans heavily on immutability, composition, and pipelining.

Just because Nushell variables are immutable doesn’t mean things don’t change. Nushell makes heavy use of the technique of “shadowing”. Shadowing means creating a new variable with the same name as a previously declared variable. For example, say you had an **\$x** in scope, and you wanted a new **\$x** that was one greater:

```
let x = $x + 1
```

This new **x** is visible to any code that follows this line. Careful use of shadowing can make for an easier time working with variables, though it’s not required.

Loop counters are another common pattern for mutable variables and are built into most iterating commands, for example you can get both each item and an index of each item using the **-n** flag on **each**:

```
> ls | each -n { |it| $"Number ($it.index) is size ($it.item.size)" }
```

You can also use the **reduce** command to work in the same way you might mutate a variable in a loop. For example, if you wanted to find the largest string in a list of strings, you might do:

```
> [one, two, three, four, five, six] | reduce {|curr, max|
  if ($curr | str length) > ($max | str length) {
    $curr
  } else {
    $max
  }
}
```

**Thinking in Nushell:** If you're used to using mutable variables for different tasks, it will take some time to learn how to do each task in a more functional style. Nushell has a set of built-in capabilities to help with many of these patterns, and learning them will help you write code in a more Nushell-style. The added benefit of speeding up your scripts by running parts of your code in parallel is a nice bonus.

## Nushell's environment is scoped

Nushell takes multiple design cues from compiled languages. One such cue is that languages should avoid global mutable state. Shells have commonly used global mutation to update the environment, but Nushell steers clear of this approach.

In Nushell, blocks control their own environment. Changes to the environment are scoped to the block where they happen.

In practice, this lets you write some concise code for working with subdirectories, for example, if you wanted to build each sub-project in the current directory, you could run:

```
> ls | each { |it|
  cd $it.name
  make
}
```

The `cd` command changes the `PWD` environment variables, and this variable change does not escape the block, allowing each iteration to start from the current directory and enter the next subdirectory.

Having the environment scoped like this makes commands more predictable, easier to read, and when the time comes, easier to debug. Nushell also provides helper commands like `def-env`, `load-env`, as convenient ways of doing batches of updates to the environment.

\* - there is one exception here, where `def-env` allows you to create a command that participates in the caller's environment

**Thinking in Nushell:** - The coding best practice of no global mutable variables extends to the environment in Nushell. Using the built-in helper commands will let you more easily work with the environment in Nushell. Taking advantage of the fact that environments are scoped to blocks can also help you write more concise scripts and interact with external commands without adding things into a global environment you don't need.

## Chapter 4

# Moving around your system

Early shells allow you to move around your filesystem and run commands, and modern shells like Nu allow you to do the same. Let's take a look at some of the common commands you might use when interacting with your system.

### Viewing directory contents

```
> ls
```

As we've seen in other chapters, `ls` is a command for viewing the contents of a path. Nu will return the contents as a table that we can use.

The `ls` command also takes an optional argument, to change what you'd like to view. For example, we can list the files that end in ".md"

```
> ls *.md
```

#	name	type	size	modified
0	CODE_OF_CONDUCT.md	File	3.4 KB	5 days ago
1	CONTRIBUTING.md	File	886 B	5 days ago
2	README.md	File	15.0 KB	5 days ago

---

```
3  TODO.md           File    1.6 KB    5 days ago
```

The asterisk (\*) in the above optional argument “\*.md” is sometimes called a wildcard or a glob. It lets us match anything. You could read the glob “\*.md” as “match any filename, so long as it ends with ‘.md’ ”

Nu also uses modern globs as well, which allow you access to deeper directories.

```
ls **/*.md
```

#	name	type
size	modified	
0	.github/ISSUE_TEMPLATE/bug_report.md	File
592 B	5 days ago	
1	.github/ISSUE_TEMPLATE/feature_request.md	File
595 B	5 days ago	
2	CODE_OF_CONDUCT.md	File
3.4 KB	5 days ago	
3	CONTRIBUTING.md	File
886 B	5 days ago	
4	README.md	File
15.0 KB	5 days ago	
5	TODO.md	File
1.6 KB	5 days ago	
6	crates/nu-source/README.md	File
1.7 KB	5 days ago	
7	docker/packaging/README.md	File
1.5 KB	5 days ago	
8	docs/commands/README.md	File
929 B	5 days ago	
9	docs/commands/alias.md	File
1.7 KB	5 days ago	
10	docs/commands/append.md	File
1.4 KB	5 days ago	

Here, we’re looking for any file that ends with “.md”, and the two asterisks further say “in any directory starting from here”.

## Changing the current directory

```
> cd new_directory
```

To change from the current directory to a new one, we use the `cd` command. Just as in other shells, we can use either the name of the directory, or if we want to go up a directory we can use the `..` shortcut.

Changing the current working directory can also be done if `cd` is omitted and a path by itself is given:

```
> new_directory
```

**Note:** changing the directory with `cd` changes the `PWD` environment variable. This means that a change of a directory is kept to the current block. Once you exit the block, you'll return to the previous directory. You can learn more about working with this in the [environment chapter](#)<sup>1</sup>.

## Filesystem commands

Nu also provides some basic filesystem commands that work cross-platform.

We can move an item from one place to another using the `mv` command:

```
> mv item location
```

We can copy an item from one location to another:

```
> cp item location
```

We can remove an item:

```
> rm item
```

The three commands also can use the glob capabilities we saw earlier with `ls`.

Finally, we can create a new directory using the `mkdir` command:

---

<sup>1</sup> [./environment.md](#)

```
> mkdir new_directory
```

# Chapter 5

## Types of data

Traditionally, Unix shell commands have communicated with each other using strings of text. One command would output text via standard out (often abbreviated ‘stdout’) and the other would read in text via standard in (or ‘stdin’), allowing the two commands to communicate.

We can think of this kind of communication as string-based.

Nu embraces this approach for its commands and expands it to include other kinds of data. Currently, Nu supports two kinds of data types: simple and structured.

Like many programming languages, Nu models data using a set of simple and structured data types. Simple data types include integers, floats, strings, booleans, dates, and paths. It also includes a special type for file sizes.

### Integers

Integers (or round) numbers. Examples include 1, 5, and 100.

### Decimal

Decimal numbers are numbers with some fractional component. Examples include 1.5, 2.0, and 15.333.

## Strings

A string of characters that represents text. There are a few ways we can represent text in Nushell:

### Double quotes

```
"my message"
```

Double quotes are the most common form of quotes and one you may see whenever text is required.

### Single quotes

```
'my message'
```

Single quotes also give you a string value, just like double quotes. The difference here is that they allow you to use double quotes in the text: `'he said "can you grab my glass?'"`

**String interpolation** Nushell supports string interpolation, allowing you to run sub-expressions inside of strings prefixed with `$`. For instance:

```
> echo $"6 x 7 = (6 * 7)"  
6 x 7 = 42
```

```
> ls | each { |it| echo $"($it.name) is ($it.size)" }  
  
0  genawait is 4.1 KB  
1  learncpp is 4.1 KB  
2  nuscripts is 4.1 KB
```

### Bare strings

```
> echo hello
```

A unique trait of Nushell is that you can also create a string of one word without any quotes at all.

The above is the same as if we had written:

```
> echo "hello"
```

Also see [Working with Strings](#)<sup>1</sup>.

## Lines

Lines are strings with an implied OS-dependent line ending. When used, the OS-specific line ending is used.

## Column paths

Column paths are a path through the table to a specific sub-table, column, row, or cell.

Eg) The value `foo.0.bar` in `open data.toml | get foo.0.bar`

## Glob patterns (wildcards)

In Nushell, file operations may also allow you to pass in a glob pattern, sometimes called a ‘wildcard’. This allows you to give a pattern that may match multiple file paths.

The most general pattern is the `*`, which will match all paths. More often, you’ll see this pattern used as part of another pattern, for example `*.bak` and `temp*`.

In Nushell, we also support double `*` to talk about traversing deeper paths that are nested inside of other directories. For example, `ls **/*` will list all the non-hidden paths nested under the current directory.

In addition to `*`, there is also the `?` pattern which will match a single character. For example, you can match the word “port” by using the pattern `p???`.

## Booleans

Booleans are the state of being true or false. Rather than writing the value directly, it is often a result of a comparison.

The two values of booleans are `true` and `false`.

---

<sup>1</sup>[https://www.nushell.sh/book/loading\\_data.html#working-with-strings](https://www.nushell.sh/book/loading_data.html#working-with-strings)

## Dates

Dates and times are held together in the Date value type. Date values used by the system are timezone-aware, and by default use the UTC timezone.

Dates are in three forms, based on the RFC 3339 standard:

- A date:
  - 2022-02-02
- A date and time (in GMT):
  - 2022-02-02T14:30:00
- A date and time with timezone:
  - 2022-02-02T14:30:00+05:00

## Duration

Durations represent a length of time. A second, 5 weeks, and a year are all durations.

Eg) 1wk is the duration of one week.

This chart shows all durations currently supported:

Duration	Length
1ns	one nanosecond
1us	one microsecond
1ms	one millisecond
1sec	one second
1min	one minute
1hr	one hour
1day	one day
1wk	one week

## Ranges

A range is a way of expressing a sequence of values from start to finish. They take the form ‘start’ + ‘.’ + ‘end’. For example, the range 1..3 means the numbers 1, 2, and 3.

## Inclusive and non-inclusive ranges

Ranges are inclusive by default, meaning that the ending value is counted as part of the range. The range `1..3` includes the number 3 as the last value in the range.

Sometimes, you may want a range that comes up to a number but doesn't use that number in the output. For this case, you can use `..<` instead of `...`. For example, `1..<5` is the numbers 1, 2, 3, and 4.

## Open-ended ranges

Ranges can also be open-ended. You can remove the start or the end of the range to make it open-ended.

Let's say you wanted to start counting at 3, but you didn't have a specific end in mind. You could use the range `3..` to represent this. When you use a range that's open-ended on the right side, remember that this will continue counting for as long as possible, which could be a very long time! You'll often want to use open-ended ranges with commands like `first`, so you can take the number of elements you want from the range.

You can also make the start of the range open. In this case, Nushell will start counting with 0, and go up from there. The range `..2` is the numbers 0, 1, and 2.

## File paths

File paths are a platform-independent way of representing a file path in the given OS. Examples include `/usr/bin` and `C:\Users\file.txt`.

## File sizes

File sizes are held in a special integer type called bytes. Examples include `100b`, `15kb`, and `100mb`.

The full list of filesize units are:

- `b`: bytes
- `kb`: kilobytes (aka 1000 bytes)
- `mb`: megabytes

- **gb**: gigabytes
- **tb**: terabytes
- **pb**: petabytes
- **kib**: kibibytes (aka 1024 bytes)
- **mib**: mebibytes
- **gib**: gibibytes
- **tib**: tebibytes
- **pib**: pebibytes

## Binary data

Binary data, like the data from an image file, is a group of raw bytes.

You can write binary as a literal using any of the `0x[...]` or `0b[...]` forms:

```
> 0x[1F FF]
> 0b[1 1010]
```

Incomplete bytes will be left-padded with zeros.

## Structured data

Structured data builds from the simple data. For example, instead of a single integer, structured data gives us a way to represent multiple integers in the same value. Here's a list of the currently supported structured data types: records, lists and tables.

## Records

Records hold key-value pairs, much like objects in JSON. As these can sometimes have many fields, a record is printed up-down rather than left-right:

```
> echo {name: sam, rank: 10}

name  sam
rank  10
```

You can iterate over records by first transposing it into a table:

```
> echo {name: sam, rank: 10} | transpose key value

#   key   value
0   name   sam
1   rank   10
```

## Lists

Lists can hold more than one value. These can be simple values. They can also hold rows, and the combination of a list of records is often called a “table”.

Example: a list of strings

```
> echo [sam fred george]

0   sam
1   fred
2   george
```

## Tables

The table is a core data structure in Nushell. As you run commands, you’ll see that many of them return tables as output. A table has both rows and columns.

We can create our own tables similarly to how we create a list. Because tables also contain columns and not just values, we pass in the name of the column values:

```
> echo [[column1, column2]; [Value1, Value2]]

#   column1  column2
0   Value1   Value2
```

We can also create a table with multiple rows of data:

```
> echo [[column1, column2]; [Value1, Value2] [Value3, Value4]]

#   column1  column2
0   Value1   Value2
1   Value3   Value4
```

You can also create a table as a list of records:

```
> echo [{name: sam, rank: 10}, {name: bob, rank: 7}]

#   name  rank
0   sam   10
1   bob    7
```

## Blocks

Blocks represent a block of code in Nu. For example, in the command `each { |it| echo $it }` the block is the portion contained in curly braces, `{ |it| echo $it }`. Block parameters are specified between a pair of pipe symbols (for example, `|it|`) if necessary.

Blocks are a useful way to represent code that can be executed on each row of data. It is idiomatic to use `$it` as a parameter name in `each` blocks, but not required; `each { |x| echo $x }` works the same way as `each { |it| echo $it }`.

## Groups

Take this example:

```
foo {  
  line1  
  line2; line3 | line4  
}
```

Inside the block, you have two separate groups that run to completion, a group is a semicolon-separated list of pipelines, the last of which is output to the screen.

- `line1` is a group unto itself, so that command will run to completion and get displayed on the screen.
- `line2` is a pipeline inside of the second group. It runs, but its contents are not viewed on the screen.
- `line3 | line4` is the second pipeline in the second group. It runs, and its contents get viewed.

# Chapter 6

## Loading data

Earlier, we saw how you can use commands like `ls`, `ps`, `date`, and `sys` to load information about your files, processes, time of date, and the system itself. Each command gives us a table of information that we can explore. There are other ways we can load in a table of data to work with.

### Opening files

One of Nu's most powerful assets in working with data is the `open` command. It is a multi-tool that can work with a number of different data formats. To see what this means, let's try opening a json file:

```
> open editors/vscode/package.json
```

name	lark
description	Lark support for VS Code
author	Lark developers
license	MIT
version	1.0.0
repository	[row type url]
publisher	vscode
categories	[table 0 rows]
keywords	[table 1 rows]
engines	[row vscode]
activationEvents	[table 1 rows]

```
main                ./out/extension
contributes          [row configuration grammars languages]
scripts              [row compile postinstall test vscode:
prepublish watch]
devDependencies      [row @types/mocha @types/node tslint
typescript vscode  vscode-languageclient]
```

In a similar way to `ls`, opening a file type that Nu understands will give us back something that is more than just text (or a stream of bytes). Here we open a “package.json” file from a JavaScript project. Nu can recognize the JSON text and parse it to a table of data.

If we wanted to check the version of the project we were looking at, we can use the `get` command.

```
> open editors/vscode/package.json | get version
1.0.0
```

Nu currently supports the following formats for loading data directly into tables:

- csv
- eml
- ics
- ini
- json
- nuon
- ods
- ssv
- toml
- tsv
- url
- vcf

- `xlsx` / `xls`
- `xml`
- `yaml` / `yml`

But what happens if you load a text file that isn't one of these? Let's try it:

```
> open README.md
```

We're shown the contents of the file. If the file is too large, we get a handy scroll-view to look at the file and then jump back to the terminal. To help with readability, Nu will also syntax-highlight common file formats like source files, Markdown, and more.

Below the surface, what Nu sees in these text files is one large string. Next, we'll talk about how to work with these strings to get the data we need out of them.

## Working with strings

An important part of working with data coming from outside Nu is that it's not always in a format that Nu understands. Often this data is given to us as a string.

Let's imagine that we're given this data file:

```
> open people.txt
Octavia | Butler | Writer
Bob | Ross | Painter
Antonio | Vivaldi | Composer
```

Each bit of data we want is separated by the pipe (`|`) symbol, and each person is on a separate line. Nu doesn't have a pipe-delimited file format by default, so we'll have to parse this ourselves.

The first thing we want to do when bringing in the file is to work with it a line at a time:

```
> open people.txt | lines

0 Octavia | Butler | Writer
1 Bob | Ross | Painter
2 Antonio | Vivaldi | Composer
```

We can see that we're working with the lines because we're back into a table. Our next step is to see if we can split up the rows into something a little more useful. For that, we'll use the `split` command. `split`, as the name implies, gives us a way to split a delimited string. We will use `split`'s `column` subcommand to split the contents across multiple columns. We tell it what the delimiter is, and it does the rest:

```
> open people.txt | lines | split column "|"

#   column1      column2      column3

0   Octavia      Butler      Writer
1   Bob          Ross       Painter
2   Antonio      Vivaldi    Composer
```

That *almost* looks correct. It looks like there's an extra space there. Let's `trim` that extra space:

```
> open people.txt | lines | split column "|" | str trim

#   column1      column2      column3

0   Octavia      Butler      Writer
1   Bob          Ross       Painter
2   Antonio      Vivaldi    Composer
```

Not bad. The `split` command gives us data we can use. It also goes ahead and gives us default column names:

```
> open people.txt | lines | split column "|" | str trim
| get column1

0   Octavia
1   Bob
2   Antonio
```

We can also name our columns instead of using the default names:

```
> open people.txt | lines | split column "|" first_name
last_name job | str trim

#   first_name   last_name   job
0   Octavia     Butler     Writer
1   Bob         Ross       Painter
2   Antonio     Vivaldi    Composer
```

Now that our data is in a table, we can use all the commands we've used on tables before:

```
> open people.txt | lines | split column "|" first_name
last_name job | str trim | sort-by first_name

#   first_name   last_name   job
0   Antonio     Vivaldi    Composer
1   Bob         Ross       Painter
2   Octavia     Butler     Writer
```

There are other commands you can use to work with strings:

- `str`
- `lines`
- `size`

There is also a set of helper commands we can call if we know the data has a structure that Nu should be able to understand. For example, let's open a Rust lock file:

```
> open Cargo.lock
# This file is automatically @generated by Cargo.
# It is not intended for manual editing.
[[package]]
name = "ad hoc_derive"
version = "0.1.2"
```

The “Cargo.lock” file is actually a .toml file, but the file extension isn’t .toml. That’s okay, we can use the **from** command using the **toml** subcommand:

```
> open Cargo.lock | from toml

metadata    [row 107 columns]
package     [table 130 rows]
```

The **from** command can be used for each of the structured data text formats that Nu can open and understand by passing it the supported format as a subcommand.

## Opening in raw mode

While it’s helpful to be able to open a file and immediately work with a table of its data, this is not always what you want to do. To get to the underlying text, the **open** command can take an optional **--raw** flag:

```
> open Cargo.toml --raw
[package]
name = "nu"
version = "0.1.3"
authors = ["Yehuda Katz <wycats@gmail.com>", "Jonathan
Turner <jonathan.d.turner@gmail.com>"]
description = "A shell for the GitHub era"
license = "MIT"
```

## Fetching URLs

In addition to loading files from your filesystem, you can also load URLs by using the **fetch** command. This will fetch the contents of the URL

from the internet and return it:

```
> fetch https://www.jonathanturner.org/feed.xml  
  
rss  [row attributes children]
```

# Chapter 7

## Working with strings

Strings in Nushell help to hold text data for later use. This can include file names, file paths, names of columns, and much more. Strings are so common that Nushell offers a couple ways to work with them, letting you pick what best matches your needs.

### Single-quoted string

The simplest string in Nushell is the single-quoted string. This string uses the `'` character to surround some text. Here's the text for hello world as a single-quoted string:

```
> 'hello world'
hello world
```

Single-quoted strings don't do anything to the text they're given, making them ideal for holding a wide range of text data.

### Double-quoted strings

For more complex strings, Nushell also offers double-quoted strings. These strings use the `"` character to surround text. They also support the ability escape characters inside the text using the `\` character.

For example, we could write the text hello followed by a new line and then world, using escape characters and a double-quoted string:

```
> "hello\nworld"  
hello  
world
```

Escape characters let you quickly add in a character that would otherwise be hard to type.

Nushell currently supports the following escape characters:

- `\"` - double-quote character
- `\'` - single-quote character
- `\\` - backslash
- `\/` - forward slash
- `\b` - backspace
- `\f` - formfeed
- `\r` - carriage return
- `\n` - newline (line feed)
- `\t` - tab
- `\uXXXX` - a unicode character (replace XXXX with the number of the unicode character)

## String interpolation

More complex string use cases also need a new form of string: string interpolation. This is a way of building text from both raw text and the result of running expressions. String interpolation combines the results together, giving you a new string.

String interpolation uses `$" "` and `$' '` as ways to wrap interpolated text.

For example, let's say we have a variable called `$name` and we want to greet the name of the person contained in this variable:

```
> let name = "Alice"  
> $"greetings, ($name)"
```

```
greetings, Alice
```

By wrapping expressions in `()`, we can run them to completion and use the results to help build the string.

String interpolation has both a single-quoted, `$' '`, and a double-quoted, `$" "`, form. These correspond to the single-quoted and double-quoted strings: single-quoted string interpolation doesn't support escape characters while double-quoted string interpolation does.

As of version 0.61, interpolated strings support escaping parentheses, so that the `(` and `)` characters may be used in a string without Nushell trying to evaluate what appears between them:

```
> $"2 + 2 is (2 + 2) \ (you guessed it!)"
2 + 2 is 4 (you guessed it!)
```

## Splitting strings

The **split row** command creates a list from a string based on a delimiter. For example, `let colors = ("red,green,blue" | split row ",")` creates the list `[red green blue]`.

The **split column** command will create a table from a string based on a delimiter. For example `let colors = ("red,green,blue" | split column ",")` creates a table, giving only column to each element.

Finally, the **split chars** command will split a string into a list of characters.

## The str command

Many string functions are subcommands of the **str** command. You can get a full list using **help str**.

For example, you can look if a string contains a particular character using **str contains**:

```
> "hello world" | str contains "w"
true
```

# Chapter 8

## Working with lists

### Creating lists

A list is an ordered collection of values. You can create a `list` with square brackets, surrounded values separated by spaces and/or commas (for readability). For example, `[foo bar baz]` or `[foo, bar, baz]`.

### Updating lists

You can `update` and `insert` values into lists as they flow through the pipeline, for example let's insert the value 10 into the middle of a list:

```
> [1, 2, 3, 4] | insert 2 10
```

We can also use `update` to replace the 2nd element with the value 10.

```
> [1, 2, 3, 4] | update 1 10
```

In addition to `insert` and `update`, we also have `prepend` and `append`. These let you insert to the beginning of a list or at the end of the list, respectively.

For example:

```
let colors = [yellow green]
let colors = ($colors | prepend red)
let colors = ($colors | append purple)
```

```
echo $colors # [red yellow green purple]
```

## Iterating over lists

To iterate over the items in a list, use the **each** command with a **block** of Nu code that specifies what to do to each item. The block parameter (e.g. `|it|` in `{ |it| echo $it }`) is normally the current list item, but the `--numbered (-n)` flag can change it to have **index** and **item** values if needed. For example:

```
let names = [Mark Tami Amanda Jeremy]
$names | each { |it| $"Hello, ($it)!" }
# Outputs "Hello, Mark!" and three more similar lines.

$names | each -n { |it| $"($it.index + 1) - ($it.item)" }
# Outputs "1 - Mark", "2 - Tami", etc.
```

The **where** command can be used to create a subset of a list, effectively filtering the list based on a condition.

The following example gets all the colors whose names end in “e”.

```
let colors = [red orange yellow green blue purple]
echo $colors | where ($it | str ends-with 'e')
```

In this example, we keep only values higher than 7.

```
# The block passed to where must evaluate to a boolean.

# This outputs the list [orange blue purple].

let scores = [7 10 8 6 7]
echo $scores | where $it > 7 # [10 8]
```

The **reduce** command computes a single value from a list. It uses a block which takes 2 parameters: the current item (conventionally named `it`) and an accumulator (conventionally named `acc`). To specify an initial value for the accumulator, use the `--fold (-f)` flag. To change it to have **index** and **item** values, add the `--numbered (-n)` flag. For example:

```
let scores = [3 8 4]
echo "total =" ($scores | reduce { |it, acc| $acc + $it
}) # 15

echo "total =" ($scores | math sum) # easier approach,
same result

echo "product =" ($scores | reduce --fold 1 { |it, acc|
$acc * $it }) # 96

echo $scores | reduce -n { |it, acc| $acc + $it.index *
$it.item } # 3 + 1*8 + 2*4 = 19
```

## Accessing the list

To access a list item at a given index, use the `$name.index` form where `$name` is a variable that holds a list.

For example, the second element in the list below can be accessed with `$names.1`.

```
let names = [Mark Tami Amanda Jeremy]
$names.1 # gives Tami
```

If the index is in some variable `$index` we can use the `get` command to extract the item from the list.

```
let names = [Mark Tami Amanda Jeremy]
let index = 1
$names | get $index # gives Tami
```

The `length` command returns the number of items in a list. For example, `[red green blue] | length` outputs 3.

The `empty?` command determines whether a string, list, or table is empty. It can be used with lists as follows:

```
let colors = [red green blue]
$colors | empty? # false

let colors = []
```

```
$colors | empty? # true
```

The `in` and `not-in` operators are used to test whether a value is in a list. For example:

```
let colors = [red green blue]
'blue' in $colors # true
'yellow' in $colors # false
'gold' not-in $colors # true
```

The `any?` command determines if any item in a list matches a given condition. For example:

```
# Do any color names end with "e"?
echo $colors | any? ($it | str ends-with "e") # true

# Is the length of any color name less than 3?
echo $colors | any? ($it | str length) < 3 # false

# Are any scores greater than 7?
echo $scores | any? $it > 7 # true

# Are any scores odd?
echo $scores | any? $it mod 2 == 1 # true
```

The `all?` command determines if every item in a list matches a given condition. For example:

```
# Do all color names end with "e"?
echo $colors | all? ($it | str ends-with "e") # false

# Is the length of all color names greater than or equal
to 3?
echo $colors | all? ($it | str length) >= 3 # true

# Are all scores greater than 7?
echo $scores | all? $it > 7 # false

# Are all scores even?
```

```
echo $scores | all? $it mod 2 == 0 # false
```

## Converting the list

The **flatten** command creates a new list from an existing list by adding items in nested lists to the top-level list. This can be called multiple times to flatten lists nested at any depth. For example:

```
echo [1 [2 3] 4 [5 6]] | flatten # [1 2 3 4 5 6]

echo [[1 2] [3 [4 5 [6 7 8]]]] | flatten | flatten | flatten
# [1 2 3 4 5 6 7 8]
```

The **wrap** command converts a list to a table. Each list value will be converted to a separate row with a single column:

```
let zones = [UTC CET Europe/Moscow Asia/Yekaterinburg]

# Show world clock for selected time zones
$zones | wrap 'Zone' | upsert Time {|it| (date now | date
to-timezone $it.Zone | date format '%Y.%m.%d %H:%M')}
```

# Chapter 9

## Working with tables

One of the common ways of seeing data in Nu is through a table. Nu comes with a number of commands for working with tables to make it convenient to find what you're looking for, and for narrowing down the data to just what you need.

To start off, let's get a table that we can use:

```
> ls
```

#	name	type	size	modified
0	files.rs	File	4.6 KB	5 days ago
1	lib.rs	File	330 B	5 days ago
2	lite_parse.rs	File	6.3 KB	5 days ago
3	parse.rs	File	49.8 KB	1 day ago
4	path.rs	File	2.1 KB	5 days ago
5	shapes.rs	File	4.7 KB	5 days ago
6	signature.rs	File	1.2 KB	5 days ago

## Sorting the data

We can sort a table by calling the **sort-by** command and telling it which columns we want to use in the sort. Let's say we wanted to sort our table by the size of the file:

```
> ls | sort-by size
```

#	name	type	size	modified
0	lib.rs	File	330 B	5 days ago
1	signature.rs	File	1.2 KB	5 days ago
2	path.rs	File	2.1 KB	5 days ago
3	files.rs	File	4.6 KB	5 days ago
4	shapes.rs	File	4.7 KB	5 days ago
5	lite_parse.rs	File	6.3 KB	5 days ago
6	parse.rs	File	49.8 KB	1 day ago

We can sort a table by any column that can be compared. For example, we could also have sorted the above using the “name”, “accessed”, or “modified” columns.

## Selecting the data you want

We can select data from a table by choosing to select specific columns or specific rows. Let’s **select** a few columns from our table to use:

```
> ls | select name size
```

#	name	size
0	files.rs	4.6 KB
1	lib.rs	330 B
2	lite_parse.rs	6.3 KB
3	parse.rs	49.8 KB
4	path.rs	2.1 KB
5	shapes.rs	4.7 KB
6	signature.rs	1.2 KB

This helps to create a table that’s more focused on what we need. Next, let’s say we want to only look at the 5 smallest files in this directory:

```
> ls | sort-by size | first 5
```

#	name	type	size	modified
0	lib.rs	File	330 B	5 days ago
1	signature.rs	File	1.2 KB	5 days ago
2	path.rs	File	2.1 KB	5 days ago
3	files.rs	File	4.6 KB	5 days ago
4	shapes.rs	File	4.7 KB	5 days ago

You'll notice we first sort the table by size to get to the smallest file, and then we use the **first 5** to return the first 5 rows of the table.

You can also **skip** rows that you don't want. Let's skip the first two of the 5 rows we returned above:

```
> ls | sort-by size | first 5 | skip 2
```

#	name	type	size	modified
0	path.rs	File	2.1 KB	5 days ago
1	files.rs	File	4.6 KB	5 days ago
2	shapes.rs	File	4.7 KB	5 days ago

We've narrowed it to three rows we care about.

Let's look at a few other commands for selecting data. You may have wondered why the rows of the table are numbers. This acts as a handy way to get to a single row. Let's sort our table by the file name and then pick one of the rows with the **select** command using its row number:

```
> ls | sort-by name
```

#	name	type	size	modified
0	files.rs	File	4.6 KB	5 days ago
1	lib.rs	File	330 B	5 days ago
2	lite_parse.rs	File	6.3 KB	5 days ago

## Getting data out of a table

So far, we've worked with tables by trimming the table down to only what we need. Sometimes we may want to go a step further and only look at the values in the cells themselves rather than taking a whole column. Let's say, for example, we wanted to only get a list of the names of the files. For this, we use the **get** command:

```
> ls | get name
```

```
0 files.rs
1 lib.rs
2 lite_parse.rs
3 parse.rs
4 path.rs
5 shapes.rs
6 signature.rs
```

We now have the values for each of the filenames.

This might look like the **select** command we saw earlier, so let's put that here as well to compare the two:

```
> ls | select name
```

```
#   name
0   files.rs
```

```
1  lib.rs
2  lite_parse.rs
3  parse.rs
4  path.rs
5  shapes.rs
6  signature.rs
```

These look very similar! Let's see if we can spell out the difference between these two commands to make it clear:

- **select** - creates a new table which includes only the columns specified
- **get** - returns the values inside the column specified as a list

The one way to tell these apart looking at the table is that the column names are missing, which lets us know that this is going to be a list of values we can work with.

The **get** command can go one step further and take a path to data deeper in the table. This simplifies working with more complex data, like the structures you might find in a .json file.

## Changing data in a table

In addition to selecting data from a table, we can also update what the table has. We may want to combine tables, add new columns, or edit the contents of a cell. In Nu, rather than editing in place, each of the commands in the section will return a new table in the pipeline.

## Concatenating Tables

We can concatenate tables with identical column names using **echo**:

```
> let $first = [[a b]; [1 2]]
> let $second = [[a b]; [3 4]]
> echo $first $second

#   a   b
0   1   2
```

```
1  3  4
```

## Adding a new column

We can use the **insert** command to add a new column to the table. Let's look at an example:

```
> open rustfmt.toml

edition    2018
```

Let's add a column called "next\_edition" with the value 2021:

```
> open rustfmt.toml | insert next_edition 2021

edition      2018
next_edition 2021
```

Notice that we if open the original file, the contents have stayed the same:

```
> open rustfmt.toml

edition    2018
```

Changes in Nu are functional changes, meaning that they work on the values themselves rather than trying to cause a permanent change. This lets us do many different types of work in our pipeline until we're ready to write out the result with any changes we'd like if we choose to. Here we could write out the result using the **save** command:

```
> open rustfmt.toml | insert next_edition 2021 | save rustfmt2.
toml
> open rustfmt2.toml

edition      2018
```

```
next_edition  2021
```

## Updating a column

In a similar way to the **insert** command, we can also use the **update** command to change the contents of a column to a new value. To see it in action let's open the same file:

```
> open rustfmt.toml

edition  2018
```

And now, let's update the edition to point at the next edition we hope to support:

```
> open rustfmt.toml | update edition 2021

edition  2021
```

You can also use the **upsert** command to insert or update depending on whether the column already exists.

## Moving columns

You can use **move** to move columns in the table. For example, if we wanted to move the “name” column from **ls** after the “size” column, we could do:

```
> ls | move name --after size
```

#	type	size	name	modified
0	dir	256 B	Applications	3 days ago
1	dir	256 B	Data	2 weeks ago

2	dir	448 B	Desktop	2 hours ago
3	dir	192 B	Disks	a week ago
4	dir	416 B	Documents	4 days ago
...				

## Renaming columns

You can also **rename** columns in a table by passing it through the `rename` command. If we wanted to run `ls` and rename the columns, we can use this example:

```
> ls | rename filename filetype filesize date
```

#	filename	filetype	filesize	date
0	Applications	dir	256 B	3 days ago
1	Data	dir	256 B	2 weeks ago
2	Desktop	dir	448 B	2 hours ago
3	Disks	dir	192 B	a week ago
4	Documents	dir	416 B	4 days ago
...				

# Chapter 10

## Pipelines

One of the core designs of Nu is the pipeline, a design idea that traces its roots back decades to some of the original philosophy behind Unix. Just as Nu extends from the single string data type of Unix, Nu also extends the idea of the pipeline to include more than just text.

### Basics

A pipeline is composed of three parts: the input, the filter, and the output.

```
> open "Cargo.toml" | inc package.version --minor | save  
"Cargo_new.toml"
```

The first command, `open "Cargo.toml"`, is an input (sometimes also called a “source” or “producer”). This creates or loads data and feeds it into a pipeline. It’s from input that pipelines have values to work with. Commands like `ls` are also inputs, as they take data from the filesystem and send it through the pipelines so that it can be used.

The second command, `inc package.version --minor`, is a filter. Filters take the data they are given and often do something with it. They may change it (as with the `inc`<sup>1</sup> command in our example), or they may do another operation, like logging, as the values pass through.

The last command, `save "Cargo_new.toml"`, is an output (sometimes called a “sink”). An output takes input from the pipeline and

---

<sup>1</sup> `commands/inc.md`

does some final operation on it. In our example, we save what comes through the pipeline to a file as the final step. Other types of output commands may take the values and view them for the user.

## Multi-line pipelines

If a pipeline is getting a bit long for one line, you can enclose it within `(` and `)` to create a subexpression:

```
(  
    "01/22/2021" |  
    parse "{month}/{day}/{year}" |  
    get year  
)
```

Also see [Subexpressions](#)<sup>2</sup>

## Working with external commands

Nu commands communicate with each other using the Nu data types (see [types of data](#)), but what about commands outside of Nu? Let's look at some examples of working with external commands:

```
internal_command | external_command
```

Data will flow from the `internal_command` to the `external_command`. This data will get converted to a string, so that they can be sent to the `stdin` of the `external_command`.

```
external_command | internal_command
```

Data coming from an external command into Nu will come in as bytes that Nushell will try to automatically convert to UTF-8 text. If successful, a stream of text data will be sent to `internal_command`. If unsuccessful, a stream of binary data will be sent to `internal_command`. Commands like [lines](#) help make it easier to bring in data from external commands, as it gives discrete lines of data to work with.

```
external_command_1 | external_command_2
```

Nu works with data piped between two external commands in the same way as other shells, like Bash would. The `stdout` of `external_command_1` is connected to the `stdin` of `external_command_2`. This lets data flow naturally between the two commands.

---

<sup>2</sup>[https://www.nushell.sh/book/variables\\_and\\_subexpressions.html#subexpressions](https://www.nushell.sh/book/variables_and_subexpressions.html#subexpressions)

## Behind the scenes

You may have wondered how we see a table if `ls` is an input and not an output. Nu adds this output for us automatically using another command called `table`. The `table` command is appended to any pipeline that doesn't have an output. This allows us to see the result.

In effect, the command:

```
> ls
```

And the pipeline:

```
> ls | table
```

Are one and the same.

# Chapter 11

## Custom commands

Nu's ability to compose long pipelines allow you a lot of control over your data and system, but it comes at the price of a lot of typing. Ideally, you'd be able to save your well-crafted pipelines to use again and again.

This is where custom commands come in.

An example definition of a custom command:

```
def greet [name] {  
    echo "hello" $name  
}
```

In this definition, we define the **greet** command, which takes a single parameter **name**. Following this parameter is the block that represents what will happen when the custom command runs. When called, the custom command will set the value passed for **name** as the **\$name** variable, which will be available to the block.

To run the above, we can call it like we would call built-in commands:

```
> greet "world"
```

As we do, we also get output just as we would with built-in commands:

```
0  hello  
1  world
```

## Command names

In Nushell, a command name is a string of characters or a quoted string. Here are some examples of valid command names: `greet`, `get-size`, `mycommand123`, `"mycommand"`, `,`, and `123`.

*Note: It's common practice in Nushell to separate the words of the command with `-` for better readability.* For example `get-size` instead of `getsize` or `get_size`.

## Sub-commands

You can also define subcommands to commands using a space. For example, if we wanted to add a new subcommand to `str`, we can create it by naming our subcommand to start with “`str` “. For example:

```
def "str mycommand" [] {  
    echo hello  
}
```

Now we can call our custom command as if it were a built-in subcommand of `str`:

```
> str mycommand
```

## Parameter types

When defining custom commands, you can name and optionally set the type for each parameter. For example, you can write the above as:

```
def greet [name: string] {  
    echo "hello" $name  
}
```

The types of parameters are optional. Nushell supports leaving them off, and treating the parameter as `any` if so. If you annotated a type on a parameter, Nushell will check this type when you call the function.

For example, let's say you wanted to take in an `int` instead:

```
def greet [name: int] {  
    echo "hello" $name  
}  
  
greet world
```

If we try to run the above, Nushell will tell us that the types don't match:

```
error: Type Error  
      shell:6:7  
  
5   greet world  
      ~~~~~ Expected int, found world
```

This can help you guide users of your definitions to call them with only the supported types.

The currently accepted types are (as of version 0.59.0):

- any
- block
- cell-path
- duration
- path
- expr
- filesize
- glob
- int
- math
- number
- operator
- range

- `cond`
- `bool`
- `signature`
- `string`
- `variable`

## Optional positional parameters

By default, positional parameters are required. If a positional parameter is not passed, we will encounter an error:

```
× Missing required positional argument.
  [entry #23:1:1]
1  greet
   .
   .      missing name

help: Usage: greet <name>
```

We can instead mark a positional parameter as optional by putting a question mark (?) after its name. For example:

```
def greet [name?: string] {
  echo "hello" $name
}

greet
```

Making a positional parameter optional does not change its name when accessed in the body. As the example above shows, it is still accessed with `$name`, despite the `?` suffix in the parameter list.

When an optional parameter is not passed, its value in the command body is equal to `null` and `$nothing`. We can use this to act on the case where a parameter was not passed:

```
def greet [name?: string] {
  if ($name == null) {
    echo "hello, I don't know your name!"
  }
}
```

```
    } else {  
        echo "hello" $name  
    }  
}  
  
greet
```

If required and optional positional parameters are used together, then the required parameters must appear in the definition first.

## Flags

In addition to passing positional parameters, you can also pass named parameters by defining flags for your custom commands.

For example:

```
def greet [  
    name: string  
    --age: int  
] {  
    echo $name $age  
}
```

In the **greet** definition above, we define the **name** positional parameter as well as an **age** flag. This allows the caller of **greet** to optionally pass the **age** parameter as well.

You can call the above using:

```
> greet world --age 10
```

Or:

```
> greet --age 10 world
```

Or even leave the flag off altogether:

```
> greet world
```

Flags can also be defined to have a shorthand version. This allows you to pass a simpler flag as well as a longhand, easier-to-read flag.

Let's extend the previous example to use a shorthand flag for the `age` value:

```
def greet [  
  name: string  
  --age (-a): int  
] {  
  echo $name $age  
}
```

*Note:* Flags are named by their longhand name, so the above example would need to use `$age` and not `$a`.

Now, we can call this updated definition using the shorthand flag:

```
> greet -a 10 hello
```

## Rest parameters

There may be cases when you want to define a command which takes any number of positional arguments. We can do this with a rest parameter, using the following ... syntax:

```
def greet [...name: string] {  
  echo "hello all:"  
  for $n in $name {  
    echo $n  
  }  
}  
  
greet earth mars jupiter venus
```

We could call the above definition of the `greet` command with any number of arguments, including none at all. All of the arguments are collected into `$name` as a list.

Rest parameters can be used together with positional parameters:

```
def greet [vip: string, ...name: string] {
    echo "hello to our VIP" $vip
    echo "and hello to everybody else:"
    for $n in $name {
        echo $n
    }
}

#      $vip      $name
#      ---- -----
greet moon earth mars jupiter venus
```

## Documenting your command

In order to best help users of your custom commands, you can also document them with additional descriptions for the commands and the parameters.

Taking our previous example:

```
def greet [
    name: string
    --age (-a): int
] {
    echo $name $age
}
```

Once defined, we can run **help greet** to get the help information for the command:

```
Usage:
  > greet <name> {flags}

Parameters:
  <name>

Flags:
  -h, --help: Display this help message
  -a, --age <integer>
```

You can see the parameter and flag that we defined, as well as the `-h` help flag that all commands get.

To improve this help, we can add descriptions to our definition that will show up in the help:

```
# A greeting command that can greet the caller
def greet [
  name: string      # The name of the person to greet
  --age (-a): int   # The age of the person
] {
  echo $name $age
}
```

The comments that we put on the definition and its parameters then appear as descriptions inside the `help` of the command.

Now, if we run `help greet`, we're given a more helpful help text:

```
A greeting command that can greet the caller

Usage:
  > greet <name> {flags}

Parameters:
  <name> The name of the person to greet

Flags:
  -h, --help: Display this help message
  -a, --age <integer>: The age of the person
```

## Pipeline Output

Custom commands stream their output just like built-in commands. For example, let's say we wanted to refactor this pipeline:

```
> ls | get name
```

Let's move `ls` into a command that we've written:

```
def my-ls [] { ls }
```

We can use the output from this command just as we would **ls**.

```
> my-ls | get name

0  myscript.nu
1  myscript2.nu
2  welcome_to_nushell.md
```

This lets us easily build custom commands and process their output. Note, we don't use return statements like other languages. Instead, we build pipelines that output streams of data that can be connected to other pipelines.

## Pipeline Input

Custom commands can also take input from the pipeline, just like other commands. This input is automatically passed to the block that the custom command uses.

Let's make our own command that doubles every value it receives as input:

```
def double [] {
  each { |it| 2 * $it }
}
```

Now, if we call the above command later in a pipeline, we can see what it does with the input:

```
> [1 2 3] | double

0  2
1  4
2  6
```

## Persisting

For information about how to persist custom commands so that they're visible when you start up Nushell, see the [configuration chapter](#) and add your startup script.

# Chapter 12

## Aliases

Aliases in Nushell offer a way of doing a simple, textual replacement. This allows you to create a shorthand name for a longer command, including its default arguments.

For example, let's create an alias called `ll` which will expand to `ls -l`.

```
> alias ll = ls -l
```

We can now call this alias:

```
> ll
```

Once we do, it's as if we typed `ls -l`. This also allows us to pass in flags or positional parameters. For example, we can now also write:

```
> ll -a
```

And get the equivalent to having typed `ls -l -a`.

## Persisting

For information about how to persist aliases so that they're visible when you start up Nushell, see the [configuration chapter](#).

# Chapter 13

## Operators

Nushell supports the following operators for common math, logic, and string operations:

Operator	Description
<code>+</code>	add
<code>-</code>	subtract
<code>*</code>	multiply
<code>/</code>	divide
<code>**</code>	exponentiation (power)
<code>mod</code>	modulo
<code>==</code>	equal
<code>!=</code>	not equal
<code>&lt;</code>	less than
<code>&lt;=</code>	less than or equal
<code>&gt;</code>	greater than
<code>&gt;=</code>	greater than or equal
<code>=~</code>	regex match / string contains another
<code>!~</code>	inverse regex match / string does <i>not</i> contain another
<code>in</code>	value in list
<code>not-in</code>	value not in list
<code>&amp;&amp;</code>	and two Boolean values
<code>,</code>	

Parentheses can be used for grouping to specify evaluation order or for calling commands and using the results in an expression.

## Order of operations

Math operations are evaluated in the follow order (from highest precedence to lowest):

- Parentheses `()`
- Multiply `*` and Divide `/` and Power `**`
- Add `+` and Subtract `-`

```
> 3 * (1 + 2)
9
```

## Regular Expression / string-contains Operators

The `=~` and `!~` operators provide a convenient way to evaluate **regular expressions**<sup>1</sup>. You don't need to know regular expressions to use them - they're also an easy way to check whether 1 string contains another.

- `string =~ pattern` returns **true** if `string` contains a match for `pattern`, and **false** otherwise.
- `string !~ pattern` returns **false** if `string` contains a match for `pattern`, and **true** otherwise.

For example:

```
foobarbaz =~ bar # returns true
foobarbaz !~ bar # returns false
ls | where name =~ ^nu # returns all files whose names
start with "nu"
```

Both operators use **the Rust regex crate's `is_match()` function**<sup>2</sup>.

---

<sup>1</sup><https://cheatography.com/davechild/cheat-sheets/regular-expressions/>

<sup>2</sup>[https://docs.rs/regex/latest/regex/struct.Regex.html#method.is\\_match](https://docs.rs/regex/latest/regex/struct.Regex.html#method.is_match)

## Case Sensitivity

Operators are usually case-sensitive when operating on strings. There are a few ways to do case-insensitive work instead:

1. In the regular expression operators, specify the `(?i)` case-insensitive mode modifier:

```
"FOO" =~ "foo" # returns false
"FOO" =~ "(?i)foo" # returns true
```

2. Use the `str contains` command's `--insensitive` flag:

```
"FOO" | str contains --insensitive "foo"
```

3. Convert strings to lowercase with `str downcase` before comparing:

```
("FOO" | str downcase) == ("Foo" | str downcase)
```

# Chapter 14

## Variables and Subexpressions

There are two types of evaluation expressions in Nushell: variables and subexpressions. You know that you're looking at an evaluation expression because it begins with a dollar sign (\$). This indicates that when Nushell gets the value in this position, it will need to run an evaluation step to process the expression and then use the resulting value. Both evaluation expression forms support a simple form and a 'path' form for working with more complex data.

### Variables

The simpler of the two evaluation expressions is the variable. During evaluation, a variable is replaced by its value.

If we create a variable, we can print its contents by using \$ to refer to it:

```
> let my-value = 4
> echo $my-value
4
```

Variables in Nushell are immutable, that means that you can not change its value after declaration. They can be shadowed in nested block, that results in:

```
> let my-value = 4
> do { let my-value = 5; echo $my-value }
5
> echo $my-value
4
```

## Variable paths

A variable path works by reaching inside of the contents of a variable, navigating columns inside of it, to reach a final value. Let's say instead of 4, we had assigned a table value:

```
> let my-value = [[name]; [testuser]]
```

We can use a variable path to evaluate the variable `$my-value` and get the value from the `name` column in a single step:

```
> echo $my-value.name
testuser
```

## Subexpressions

You can always evaluate a subexpression and use its result by wrapping the expression with parentheses `()`. Note that previous versions of Nushell (prior to 0.32) used `$()`.

The parentheses contain a pipeline that will run to completion, and the resulting value will then be used. For example, `(ls)` would run the `ls` command and give back the resulting table and `(git branch --show-current)` runs the external git command and returns a string with the name of the current branch. You can also use parentheses to run math expressions like `(2 + 3)`.

Subexpressions can also be pipelines and not just single commands. If we wanted to get a list of filenames larger than ten kilobytes, we can use an subexpression to run a pipeline and assign this to a variable:

```
> let names-of-big-files = (ls | where size > 10kb)
> echo $names-of-big-files
```

#	name	type	size	modified
0	Cargo.lock	File	155.3 KB	17 hours ago
1	README.md	File	15.9 KB	17 hours ago

## Subexpressions and paths

Subexpressions also support paths. For example, let's say we wanted to get a list of the filenames in the current directory. One way to do this is to use a pipeline:

```
> ls | get name
```

We can do a very similar action in a single step using a subexpression path:

```
> echo (ls).name
```

It depends on the needs of the code and your particular style which form works best for you.

## Short-hand subexpressions (row conditions)

Nushell supports accessing columns in a subexpression using a simple short-hand. You may have already used this functionality before. If, for example, we wanted to only see rows from **ls** where the entry is at least ten kilobytes we can write:

```
> ls | where size > 10kb
```

The **where size > 10kb** is a command with two parts: the command name **where** and the short-hand expression **size > 10kb**. We say short-hand because **size** here is the shortened version of writing **\$it.size**. This could also be written in any of the following ways:

```
> ls | where $it.size > 10kb
> ls | where ($it.size > 10kb)
> ls | where {|$it| $it.size > 10kb }
```

|

For short-hand syntax to work, the column name must appear on the left-hand side of the operation (like `size in size > 10kb`).

# Chapter 15

## Scripts

In Nushell, you can write and run scripts in the Nushell language. To run a script, you can pass it as an argument to the `nu` commandline application:

```
> nu myscript.nu
```

This will run the script to completion in a new instance of Nu. You can also run scripts inside the *current* instance of Nu using **source**:

```
> source myscript.nu
```

Let's look at an example script file:

```
# myscript.nu
def greet [name] {
  echo "hello" $name
}

greet "world"
```

A script file defines the definitions for custom commands as well as the main script itself, which will run after the custom commands are defined.

In the above, first **greet** is defined by the Nushell interpreter. This allows us to later call this definition. We could have written the above as:

```
greet "world"

def greet [name] {
  echo "hello" $name
}
```

There is no requirement that definitions have to come before the parts of the script that call the definitions, allowing you to put them where you feel comfortable.

## How scripts are processed

In a script, definitions run first. This allows us to call the definitions using the calls in the script.

After the definitions run, we start at the top of the script file and run each group of commands one after another.

## Script lines

To better understand how Nushell sees lines of code, let's take a look at an example script:

```
a
b; c | d
```

When this script is run, Nushell will first run the **a** command to completion and view its results. Next, Nushell will run **b; c | d** following the rules in the **“Groups” section**.

## Parameterizing Scripts

Script files can optionally contain a special “main” command. **main** will be run after any other Nu code, and is primarily used to add parameters to scripts. You can pass arguments to scripts after the script name (**nu <script name> <script args>**).

For example:

```
# myscript.nu

def main [x: int] {
  $x + 10
}
```

```
> nu myscript.nu 100
110
```

## Shebangs (!#)

On Linux and macOS you can optionally use a [shebang<sup>1</sup>](https://en.wikipedia.org/wiki/Shebang_(Unix)) to tell the OS that a file should be interpreted by Nu. For example, with the following in a file named `myscript`:

```
#!/usr/bin/env nu
echo "Hello World!"
```

```
> ./myscript
Hello World!
```

---

<sup>1</sup>[https://en.wikipedia.org/wiki/Shebang\\_\(Unix\)](https://en.wikipedia.org/wiki/Shebang_(Unix))

# Chapter 16

## Modules

Similar to many other programming languages, Nushell also has modules that let you import custom commands into a current scope. However, since Nushell is also a shell, modules allow you to import environment variables which can be used to conveniently activate/deactivate various environments.

*Note! The current implementation of modules is quite bare-bones and will be expanded in the future. For example, it is not yet possible to import a module from within a module.*

### Basics

A simple module can be defined like this:

```
> module greetings {  
    export def hello [name: string] {  
        $"hello ($name)!"  
    }  
  
    export def hi [where: string] {  
        $"hi ($where)!"  
    }  
}
```

or in a file named the same as the the module you want to create:

```
# greetings.nu

export def hello [name: string] {
    $"hello ($name)!"
}

export def hi [where: string] {
    $"hi ($where)!"
}
```

We defined `hello` and `hi` custom commands inside a `greetings` module.

The `export` keyword makes it possible to later import the commands from the module.

Similar to `def`, it is also possible to mark `def-env` with the `export` keyword (you can learn more about `def-env` in the [Environment](#) chapter).

## Using modules

By itself, the module does not do anything. To use what the module exports, we need to `use` it.

```
> use greetings

> greetings hello "world"
hello world!

> greetings hi "there"
hi there!
```

The `hello` and `hi` commands are now available with the `greetings` prefix.

## Importing symbols

In general, anything after the `use` keyword forms an **import pattern** which controls how the symbols are imported. The import pattern can be one of the following:

```
use greetings
```

Imports all symbols with the module name as a prefix (we saw this in the previous example).

```
use greetings hello
```

The `hello` symbol will be imported directly without any prefix.

```
use greetings [ hello, hi ]
```

Imports multiple symbols directly without any prefix

```
use greetings *
```

You can also use the module name and the `*` glob to import all names directly without any prefix

## Module Files

Nushell lets you implicitly treat a source file as a module. Let's start by saving the body of the module definition into a file:

```
# greetings.nu

export def hello [name: string] {
    $"hello ($name)!"
}

export def hi [where: string] {
    $"hi ($where)!"
}
```

Now, you can call `use` directly on the file:

```
> use greetings.nu

> greetings hello "world"
hello world!

> greetings hi "there"
hi there!
```

Nushell automatically infers the module's name from the stem of the file ("greetings" without the ".nu" extension). You can use any import patterns as described above with the file name instead of the module name.

## Local Custom Commands

Any custom commands defined in a module without the `export` keyword will work only in the module's scope:

```
# greetings.nu

export def hello [name: string] {
    greetings-helper "hello" "world"
}

export def hi [where: string] {
    greetings-helper "hi" "there"
}

def greetings-helper [greeting: string, subject: string]
{
    "$($greeting) ($subject)!"
}
```

Then, in Nushell we import all definitions from the “greetings.nu”:

```
> use greetings.nu *

> hello "world"
hello world!

> hi "there"
hi there!

> greetings-helper "foo" "bar" # fails because 'greetings-
helper' is not exported
```

## Environment Variables

So far we used modules just to import custom commands. It is possible to export environment variables the same way. The syntax is slightly different than what you might be used to from commands like `let-env` or `load-env`:

```
# greetings.nu

export env MYNAME { "Arthur, King of the Britons" }

export def hello [name: string] {
    $"hello ($name)"
}
```

`use` works the same way as with custom commands:

```
> use greetings.nu

> $env."greetings MYNAME"
Arthur, King of the Britons

> greetings hello $env."greetings MYNAME"
hello Arthur, King of the Britons!
```

You can notice we do not assign the value to `MYNAME` directly. Instead, we give it a block of code (`{ ... }`) that gets evaluated every time we call `use`. We can demonstrate this property, for example, with the `random` command:

```
> module roll { export env ROLL { random dice | into string } }

> use roll ROLL

> $env.ROLL
4

> $env.ROLL
4

> use roll ROLL

> $env.ROLL
6

> $env.ROLL
6
```

## Exporting symbols

As mentioned above, you can export definitions and environment variables from modules. This lets you more easily group related definitions together and export the ones you want to make public.

You can also export aliases and externs, giving you a way to only use these features when you need. Exporting externs also gives you the ability to hide custom completion commands in a module, so they don't have to be part of the global namespace.

Here's the full list of ways you can export:

- `export def` - export a custom command
- `export def-env` - export a custom environment command
- `export env` - export an environment variable
- `export alias` - export an alias
- `export extern` - export a known external definition

## Hiding

Any custom command, alias or environment variable, imported from a module or not, can be “hidden”, restoring the previous definition. (Note, it is not yet possible to export aliases from modules but they can still be hidden.) We do this with the `hide` command:

```
> def foo [] { "foo" }  
  
> foo  
foo  
  
> hide foo  
  
> foo # error! command not found!
```

The `hide` command also accepts import patterns, just like `use`. The import pattern is interpreted slightly differently, though. It can be one of the following:

```
hide foo or hide greetings
```

- If the name is a custom command or an environment variable, hides it directly. Otherwise:
- If the name is a module name, hides all of its exports prefixed with the module name

```
hide greetings hello
```

- Hides only the prefixed command / environment variable

```
hide greetings [hello, hi]
```

- Hides only the prefixed commands / environment variables

```
hide greetings *
```

- Hides all of the module's exports, without the prefix

Let's show these with examples. We saw direct hiding of a custom command already. Let's try environment variables:

```
> let-env FOO = "FOO"

> $env.FOO
FOO

> hide FOO

> $env.FOO # error! environment variable not found!
```

The first case also applies to commands / environment variables brought from a module (using the “greetings.nu” file defined above):

```
> use greetings.nu *

> $env.MYNAME
Arthur, King of the Britons

> hello "world"
hello world!

> hide MYNAME

> $env.MYNAME # error! environment variable not found!
```

```
> hide hello

> hello "world" # error! command not found!
```

And finally, when the name is the module name (assuming the previous `greetings` module):

```
> use greetings.nu

> $env."greetings MYNAME"
Arthur, King of the Britons

> greetings hello "world"
hello world!

> hide greetings

> $env."greetings MYNAME" # error! environment variable
not found!

> greetings hello "world" # error! command not found!
```

## Chapter 17

# Configuration

### Nushell Configuration with `env.nu` and `config.nu`

Nushell uses a configuration system that loads+runs two Nushell script files at launch time: First, `env.nu`, then `config.nu`. Paths to these files can be found by calling `echo $nu.env-path` and `echo $nu.config-path`. `env.nu` is meant to define the environment variables which are then available within `config.nu`. `config.nu` can be used to add definitions, aliases, and more to the global namespace.

*(You can think of the Nushell config loading sequence as executing two `REPL`<sup>1</sup> lines on startup: `source /path/to/env.nu` and `source /path/to/config.nu`. Therefore, using `env.nu` for environment and `config.nu` for other config is just a convention.)*

When you launch Nushell without these files set up, Nushell will prompt you to download the `default env.nu`<sup>2</sup> and `default config.nu`<sup>3</sup>. You can browse the default files for default values of environment variables and a list of all configurable settings.

---

<sup>1</sup>[https://en.wikipedia.org/wiki/Read%E2%80%93eval%E2%80%93print\\_loop](https://en.wikipedia.org/wiki/Read%E2%80%93eval%E2%80%93print_loop)

<sup>2</sup>[https://github.com/nushell/nushell/blob/main/docs/sample\\_config/default\\_env.nu](https://github.com/nushell/nushell/blob/main/docs/sample_config/default_env.nu)

<sup>3</sup>[https://github.com/nushell/nushell/blob/main/docs/sample\\_config/default\\_config.nu](https://github.com/nushell/nushell/blob/main/docs/sample_config/default_config.nu)

## Configuring `$config`

Nushell's main settings are kept in the global `$config` variable as a record. This record can be created using:

```
let $config = {  
  ...  
}
```

You can also shadow `$config` and update it:

```
let $config = ($config | upsert <field name> <field value>)
```

By convention, this variable is defined in the `config.nu` file.

## Environment

You can set environment variables for the duration of a Nushell session using `let-env` calls inside the `env.nu` file. For example:

```
let-env FOO = 'BAR'
```

These are some important variables to look at for Nushell-specific settings:

- `LS_COLORS`: Sets up colors per file type in `ls`
- `PROMPT_COMMAND`: Code to execute for setting up the prompt (block or string)
- `PROMPT_COMMAND_RIGHT`: Code to execute for setting up the right prompt (block)
- `PROMPT_INDICATOR` = " ": The indicator printed after the prompt (by default ">"-like Unicode symbol)
- `PROMPT_INDICATOR_VI_INSERT` = ": "
- `PROMPT_INDICATOR_VI_NORMAL` = " "
- `PROMPT_MULTILINE_INDICATOR` = "::: "

## Color Config section

You can learn more about setting up colors and theming in the [associated chapter](#)<sup>4</sup>.

## Configuring Nu as a login shell

To use Nu as a login shell, you'll need to configure the `$env` variable. With this, you'll have enough support to run external commands as a login shell.

You can build the full set of environment variables by running Nu inside of another shell, like Bash. Once you're in Nu, you can run a command like this:

```
> env | each { |it| echo $"let-env ($it.name) = '($it.raw)
'" } | str collect (char nl)
```

This will print out `let-env` lines, one for each environment variable along with its setting.

Next, on some distros you'll also need to ensure Nu is in the `/etc/shells` list:

```
> cat /etc/shells
# /etc/shells: valid login shells
/bin/sh
/bin/dash
/bin/bash
/bin/rbash
/usr/bin/screen
/usr/bin/fish
/home/jonathan/.cargo/bin/nu
```

With this, you should be able to `chsh` and set Nu to be your login shell. After a logout, on your next login you should be greeted with a shiny Nu prompt.

## macOS: Keeping `/usr/bin/open` as `open`

Some tools (e.g. Emacs) rely on an `open` command to open files on Mac. As Nushell has its own `open` command which has different semantics

<sup>4</sup>[https://github.com/nushell/nushell/blob/main/docs/How\\_To\\_Coloring\\_and\\_Theming.md](https://github.com/nushell/nushell/blob/main/docs/How_To_Coloring_and_Theming.md)

and shadows `/usr/bin/open`, these tools will error out when trying to use it. One way to work around this is to define a custom command for Nushell's `open` and create an alias for the system's `open` in your `config.nu` file like this:

```
def nuopen [arg, --raw (-r)] { if $raw { open -r $arg }  
  else { open $arg } }  
alias open = ^open
```

## Prompt configuration

Third-party prompts now have their [own section in the Nushell book](#).

# Chapter 18

## Environment

A common task in a shell is to control the environment that external applications will use. This is often done automatically, as the environment is packaged up and given to the external application as it launches. Sometimes, though, we want to have more precise control over what environment variables an application sees.

You can see the current environment variables using the `env` command:

#	name	type
value	raw	
16	DISPLAY	string :0
17	EDITOR	string nvim
28	LANG	string en_US.
UTF-8	en_US.UTF-8	
35	PATH	list<unknown> [list
16 items]	/path1:/path2:/...	
36	PROMPT_COMMAND	block <Block
197>		

In Nushell, environment variables can be any value and have any type (see the `type` column). The actual value of the env. variable used within Nushell is under the `value` column. You can query the value directly using the `$env` variable, for example, `$env.PATH | length`.

The last **raw** column shows the actual value that will be sent to external applications (see [Environment variable conversions](#)<sup>1</sup> for details).

The environment is initially created from the Nu [configuration file](#) and from the environment that Nu is run inside of.

## Setting environment variables

There are several ways to set an environment variable:

### **let-env**

Using the **let-env** command is the most straightforward method

```
> let-env FOO = 'BAR'
```

'let-env' is similar to the **export** command in bash.

So if you want to extend the **PATH** variable for example, you could do that as follows.

```
let-env PATH = ($env.PATH | prepend '/path/you/want/to/
add')
```

Here we've prepended our folder to the existing folders in the **PATH**, so it will have the highest priority. If you want to give it the lowest priority instead, you can use the **append** command.

### **load-env**

If you have more than one environment variable you'd like to set, you can use **load-env** to create a table of name/value pairs and load multiple variables at the same time:

```
> load-env { "BOB": "FOO", "JAY": "BAR" }
```

## One-shot environment variables

These are defined to be active only temporarily for a duration of executing a code block. See [Single-use environment variables](#) for details.

---

<sup>1</sup>[#environment-variable-conversions](#)

## Calling a command defined with **def-env**

See [Defining environment from custom commands](#) for details.

## Using module's exports

See [Modules](#) for details.

## Scoping

When you set an environment variable, it will be available only in the current scope (the block you're in and any block inside of it).

Here is a small example to demonstrate the environment scoping:

```
> let-env FOO = "BAR"
> do {
  let-env FOO = "BAZ"
  $env.FOO == "BAZ"
}
true
> $env.FOO == "BAR"
true
```

## Changing directory

Common task in a shell is to change directory with the **cd** command. In Nushell, calling **cd** is equivalent to setting the **PWD** environment variable. Therefore, it follows the same rules as other environment variables (for example, scoping).

## Single-use environment variables

A common shorthand to set an environment variable once is available, inspired by Bash and others:

```
> FOO=BAR echo $env.FOO
BAR
```

You can also use **with-env** to do the same thing more explicitly:

```
> with-env { FOO: BAR } { echo $env.FOO }  
BAR
```

The **with-env** command will temporarily set the environment variable to the value given (here: the variable “FOO” is given the value “BAR”). Once this is done, the **block** will run with this new environment variable set.

## Permanent environment variables

You can also set environment variables at startup so they are available for the duration of Nushell running. To do this, set an environment variable inside **the Nu configuration file**. For example:

```
# In config.nu  
let-env FOO = 'BAR'
```

## Defining environment from custom commands

Due to the scoping rules, any environment variables defined inside a custom command will only exist inside the command’s scope. However, a command defined as **def-env** instead of **def** (it applies also to **export def**, see **Modules**) will preserve the environment on the caller’s side:

```
> def-env foo [] {  
    let-env FOO = 'BAR'  
}  
  
> foo  
  
> $env.FOO  
BAR
```

## Environment variable conversions

You can set the **ENV\_CONVERSIONS** environment variable to convert other environment variables between a string and a value. For exam-

ple, the **default config**<sup>2</sup> includes conversion of PATH (and Path used on Windows) environment variables from a string to a list. After the config loaded, any existing environment variable specified inside **ENV\_CONVERSIONS** will be translated according to its **from\_string** field into a value of any type. External tools require environment variables to be strings, therefore, any non-string environment variable needs to be converted first. The conversion of value -> string is set by the **to\_string** field of **ENV\_CONVERSIONS** and is done every time an external command is run.

Let's illustrate the conversions with an example. Put the following in your config.nu:

```
let-env ENV_CONVERSIONS = {
  # ... you might have Path and PATH already there, add:

  FOO : {
    from_string: { |s| $s | split row '-' }
    to_string: { |v| $v | str collect '-' }
  }
}
```

Now, within a Nushell instance:

```
> with-env { FOO : 'a-b-c' } { nu } # runs Nushell with
FOO env. var. set to 'a-b-c'

> $env.FOO
0   a
1   b
2   c
```

You can see the **\$env.FOO** is now a list in a new Nushell instance with the updated config. You can also test the conversion manually by

```
> do $env.ENV_CONVERSIONS.FOO.from_string 'a-b-c'
```

Now, to test the conversion list -> string, run:

---

<sup>2</sup>[https://github.com/nushell/nushell/blob/main/docs/sample\\_config/default\\_config.nu](https://github.com/nushell/nushell/blob/main/docs/sample_config/default_config.nu)

```
> nu -c '$env.FOO'
a-b-c
```

Because `nu` is an external program, Nushell translated the `[ a b c ]` according to `ENV_CONVERSIONS.FOO.to_string` and passed it to the `nu` process. Running commands with `nu -c` does not load the config file, therefore the env conversion for `FOO` is missing and it is displayed as a plain string -- this way we can verify the translation was successful. You can also run this step manually by `do $env.ENV_CONVERSIONS.FOO.to_string [a b c]`

If we look back at the `env` command, the `raw` column shows the value translated by `ENV_CONVERSIONS.<name>.to_string` and the `value` column shows the value used in Nushell (the result of `ENV_CONVERSIONS.<name>.from_string` in the case of `FOO`). If the value is not a string and does not have `to_string` conversion, it is not passed to an external (see the `raw` column of `PROMPT_COMMAND`). One exception is `PATH` (Path on Windows): By default, it converts the string to a list on startup and from a list to a string when running externals if no manual conversions are specified.

*(Important! The environment conversion string -> value happens **after** the `config.nu` is evaluated. All environment variables in `config.nu` are still strings unless you set them manually to some other values.)*

## Removing environment variables

You can remove an environment variable only if it was set in the current scope:

```
> let-env FOO = 'BAR'
...
> hide FOO
```

If you want to remove an environment variable stemming from a parent scope, you can `hide` it (see [Modules](#) for details about hiding):

```
> let-env FOO = 'BAR'
> do {
  hide FOO
  # $env.FOO does not exist
}
```

```
> $env.FOO  
BAR
```

## Chapter 19

# Stdout, Stderr, and Exit Codes

An important piece of interop between Nushell and external commands is working with the standard streams of data coming from the external.

The first of these important streams is stdout.

### Stdout

Stdout is the way that most external apps will send data into the pipeline or to the screen. Data sent by an external app to its stdout is received by Nushell by default if it's part of a pipeline:

```
> external | str collect
```

The above would call the external named **external** and would redirect the stdout output stream into the pipeline. With this redirection, Nushell can then pass the data to the next command in the pipeline, here **str collect**.

Without the pipeline, Nushell will not do any redirection, allowing it to print directly to the screen.

### Stderr

Another common stream that external applications often use to print error messages is stderr. By default, Nushell does not do any redirection

of `stderr`, which means that by default it will print to the screen.

You can force Nushell to do a redirection by using `do -i { ... }`. For example, if we wanted to call the external above and redirect its `stderr`, we would write:

```
> do -i { external }
```

## Exit code

Finally, external commands have an “exit code”. These codes help give a hint to the caller whether the command ran successfully.

Nushell tracks the last exit code of the recently completed external in one of two ways. The first way is with the `LAST_EXIT_CODE` environment variable.

```
> do -i { external }
> echo $env.LAST_EXIT_CODE
```

The second uses a command called `complete`.

## Using the `complete` command

The `complete` command allows you to run an external to completion, and gather the `stdout`, `stderr`, and exit code together in one record.

If we try to run the external `cat` on a file that doesn’t exist, we can see what `complete` does with the streams, including the redirected `stderr`:

```
> do -i { cat unknown.txt } | complete

stdout

stderr      cat: unknown.txt: No such file or directory

exit_code   1
```

## Raw streams

Both `stdout` and `stderr` are represented as “raw streams” inside of Nushell. These are streams that are streams of bytes rather than structured streams, which are what internal Nushell commands use.

Because streams of bytes can be difficult to work with, especially given how common it is to use output as it was text data, Nushell attempts to convert raw streams into text data. This allows other commands to pull on the output of external commands and receive strings they can further process.

Nushell attempts to convert to text using UTF-8. If at any time the conversion fails, the rest of the stream is assumed to always be bytes.

If you want more control over the decoding of the byte stream, you can use the `decode` command. The `decode` command can be inserted into the pipeline after the external, or other raw stream-creating command, and will handle decoding the bytes based on the argument you give `decode`. For example, you could decode shift-jis text this way:

```
> 0x[8a 4c] | decode shift-jis
```

## Chapter 20

# Escaping to the system

Nu provides a set of commands that you can use across different OSes (“internal” commands), and having this consistency is helpful. Sometimes, though, you want to run an external command that has the same name as an internal Nu command. To run the external `ls` or `date` command, for example, you use the caret (^) command. Escaping with the caret prefix calls the command that’s in the user’s PATH (e.g. `/bin/ls` instead of Nu’s internal `ls` command).

Nu internal command:

```
> ls
```

Escape to external command:

```
> ^ls
```

# Chapter 21

## How to configure 3rd party prompts

### nerdfonts

nerdfonts are not required but they make the presentation much better.

site<sup>1</sup>  
repo<sup>2</sup>

### oh-my-posh

site<sup>3</sup>  
repo<sup>4</sup>

If you like **oh-my-posh**<sup>5</sup>, you can use oh-my-posh with Nushell with a few steps. It works great with Nushell. How to setup oh-my-posh with Nushell:

1. Install Oh My Posh and download oh-my-posh's themes following **guide**<sup>6</sup>.
2. Download and install a **nerd font**<sup>7</sup>.

---

<sup>1</sup><https://www.nerdfonts.com>

<sup>2</sup><https://github.com/ryanoasis/nerd-fonts>

<sup>3</sup><https://ohmyposh.dev/>

<sup>4</sup><https://github.com/JanDeDobbeleer/oh-my-posh>

<sup>5</sup><https://ohmyposh.dev/>

<sup>6</sup><https://ohmyposh.dev/docs/linux#installation>

<sup>7</sup><https://github.com/ryanoasis/nerd-fonts>

3. Set the PROMPT\_COMMAND in ~/.config/nushell/config.nu (or the path output by \$nu.config-path), change M365Princess.omp.json to whatever you like [Themes demo](#)<sup>8</sup>.

```
> let-env PROMPT_COMMAND = { oh-my-posh --config ~/.poshthemes/
M365Princess.omp.json }
```

For MacOS users:

1. You can install oh-my-posh by **brew**, just following the [guide here](#)<sup>9</sup>
2. Download and install a [nerd font](#)<sup>10</sup>.
3. Set the PROMPT\_COMMAND in the file output by \$nu.config-path, here is a code snippet:

```
let posh-dir = (brew --prefix oh-my-posh | str trim)
let posh-theme = '$(posh-dir)/share/oh-my-posh/themes/
'
# Change the theme names to: zash/space/robbyrussel/powerline/
powerlevel10k_lean/
# material/half-life/lambda Or double lines theme: amro/
pure/spaceship, etc.
# For more [Themes demo] (https://ohmyposh.dev/docs/themes)

let-env PROMPT_COMMAND = { oh-my-posh prompt print primary
--config '$(posh-theme)/zash.omp.json' }
# Optional
let-env PROMPT_INDICATOR = $(ansi y)$> (ansi reset)"
```

## Starship

[site](#)<sup>11</sup>

[repo](#)<sup>12</sup>

---

<sup>8</sup><https://ohmyposh.dev/docs/themes>

<sup>9</sup><https://ohmyposh.dev/docs/macos>

<sup>10</sup><https://github.com/ryanoasis/nerd-fonts>

<sup>11</sup><https://starship.rs/>

<sup>12</sup><https://github.com/starship/starship>

1. Follow the links above and install Starship.
2. Install nerdfonts depending on your preferences.
3. Use the config example below. Make sure to set the `STARSHIP_SHELL` environment variable.

Here's an example config section for Starship:

```
let-env STARSHIP_SHELL = "nu"

def create_left_prompt [] {
    starship prompt --cmd-duration $env.CMD_DURATION_MS
    $'--status=($env.LAST_EXIT_CODE)'
}

# Use nushell functions to define your right and left prompt
let-env PROMPT_COMMAND = { create_left_prompt }
let-env PROMPT_COMMAND_RIGHT = ""

# The prompt indicators are environmental variables that
# represent
# the state of the prompt
let-env PROMPT_INDICATOR = ""
let-env PROMPT_INDICATOR_VI_INSERT = ": "
let-env PROMPT_INDICATOR_VI_NORMAL = " "
let-env PROMPT_MULTILINE_INDICATOR = "::: "
```

Now restart Nu.

```
nushell on  main is  v0.60.0 via  v1.59.0
```

You can learn more about configuring Starship in the [official starship configuration documentation](#)<sup>13</sup>.

An alternate way to enable Starship is described in the [Starship Quick Install](#)<sup>14</sup> instructions.

---

<sup>13</sup><https://github.com/starship/starship#step-2-setup-your-shell-to-use-starship>

<sup>14</sup><https://starship.rs/#nushell>

# Purs

repo<sup>15</sup>

---

<sup>15</sup><https://github.com/xcambar/purs>

# Chapter 22

## Shells in shells

### Working in multiple directories

While it's common to work in one directory, it can be handy to work in multiple places at the same time. For this, Nu offers the concept of “shells”. As the name implies, they're a way of running multiple shells in one, allowing you to quickly jump between working directories and more.

To get started, let's enter a directory:

```
/home/jonathant/Source/nushell(main)> enter ../book  
/home/jonathant/Source/book(main)> ls
```

#	name	type	size	modified
0	404.html	File	429 B	2 hours ago
1	CONTRIBUTING.md	File	955 B	2 hours ago
2	Gemfile	File	1.1 KB	2 hours ago
3	Gemfile.lock	File	6.9 KB	2 hours ago

Entering is similar to changing directories (as we saw with the `cd` command). This allows you to jump into a directory to work in it. Instead of changing the directory, we now are in two directories. To see this more clearly, we can use the `shells` command to list the current directories we have active:

```
/home/jonathan/Source/book(main)> shells
```

#	active	name	path
0	false	filesystem	/home/jt/Source/nushell
1	true	filesystem	/home/jt/Source/book
2	false	filesystem	/home/jt/Source/music

The **shells** command shows us there are three shells currently active: our original “nushell” source directory and now this new “book” directory.

We can jump between these shells with the **n**, **p** and **g** shortcuts, short for “next”, “previous” and “goto”:

```
/home/jonathant/Source/book(main)> n
/home/jonathant/Source/nushell(main)> p
/home/jonathant/Source/book(main)> g 2
/home/jonathant/Source/music(main)>
```

We can see the directory changing, but we’re always able to get back to a previous directory we were working on. This allows us to work in multiple directories in the same session.

## Exiting the shell

You can leave a shell you have **entered** using the **exit** command. If this is the last open shell, Nu will quit.

You can always quit Nu, even if multiple shells are active by passing the **--now** flag to the **exit** command. Like so: **exit --now**

## Chapter 23

# Reedline, Nu's line editor

Nushell's line editor **Reedline**<sup>1</sup> is a cross platform line reader designed to be modular and flexible. The engine is in charge of controlling the command history, validations, completions, hints and screen paint.

## Configuration

### Editing mode

Reedline allows you to edit text using two modes: vi and emacs. If not specified, the default edit mode is emacs mode. In order to select your favorite you need to modify your config file and write down your preferred mode.

For example:

```
let $config = {  
  ...  
  edit_mode: emacs  
  ...  
}
```

---

<sup>1</sup><https://github.com/nushell/reedline>

## Default keybindings

Each edit mode comes with the usual keybinding for vi and emacs text editing.

Emacs and Vi Insert keybindings

Key	Event
Esc	Esc
Backspace	Backspace
End	Move to end of line
End	Complete history hint
Home	Move to line start
Ctrl + c	Cancel current line
Ctrl + l	Clear screen
Ctrl + r	Search history
Ctrl + Right	Complete history word
Ctrl + Right	Move word right
Ctrl + Left	Move word left
Up	Move menu up
Up	Move up
Down	Move menu down
Down	Move down
Left	Move menu left
Left	Move left
Right	History hint complete
Right	Move menu right
Right	Move right
Ctrl + b	Move menu left
Ctrl + b	Move left
Ctrl + f	History hint complete
Ctrl + f	Move menu right
Ctrl + f	Move right
Ctrl + p	Move menu up
Ctrl + p	Move up
Ctrl + n	Move menu down
Ctrl + n	Move down

Vi Normal keybindings

Key	Event
Ctrl + c	Cancel current line
Ctrl + l	Clear screen
Up	Move menu up
Up	Move up
Down	Move menu down
Down	Move down
Left	Move menu left
Left	Move left
Right	Move menu right
Right	Move right

Besides the previous keybindings, while in Vi normal mode you can use the classic vi mode of executing actions by selecting a motion or an action. The available options for the combinations are:

#### Vi Normal motions

Key	motion
w	Word
d	Line end
0	Line start
\$	Line end
f	Right until char
t	Right before char
F	Left until char
T	Left before char

#### Vi Normal actions

Key	action
d	Delete
p	Paste after
P	Paste before
h	Move left
l	Move right
j	Move down
k	Move up
w	Move word right
b	Move word left
i	Enter Vi insert at current char
a	Enter Vi insert after char
0	Move to start of line
^	Move to start of line
\$	Move to end of line
u	Undo
c	Change
x	Delete char
s	History search
D	Delete to end
A	Append to end

## Command history

As mentioned before, Reedline manages and stores all the commands that are edited and sent to Nushell. To configure the max number of records that Reedline should store you will need to adjust this value in your config file:

```
let $config = {
  ...
  max_history_size: 1000
  ...
}
```

## Customizing your prompt

Reedline prompt is also highly customizable. In order to construct your perfect prompt, you could define the next environmental variables in your config file:

---

```
# Use nushell functions to define your right and left prompt
def create_left_prompt [] {
    let path_segment = ($env.PWD)

    $path_segment
}

def create_right_prompt [] {
    let time_segment = ([
        (date now | date format '%m/%d/%Y %r')
    ] | str collect)

    $time_segment
}

let-env PROMPT_COMMAND = { create_left_prompt }
let-env PROMPT_COMMAND_RIGHT = { create_right_prompt }
```

::: tip You don't have to define the environmental variables using Nushell functions. You can use simple strings to define them. :::

You can also customize the prompt indicator for the line editor by modifying the next env variables.

```
let-env PROMPT_INDICATOR = " "
let-env PROMPT_INDICATOR_VI_INSERT = ": "
let-env PROMPT_INDICATOR_VI_NORMAL = " "
let-env PROMPT_MULTILINE_INDICATOR = "::: "
```

::: tip The prompt indicators are environmental variables that represent the state of the prompt :::

## Keybindings

Reedline keybindings are powerful constructs that let you build chains of events that can be triggered with a specific combination of keys.

For example, let's say that you would like to map the completion menu to the `Ctrl + t` keybinding (default is `tab`). You can add the next entry to your config file.

```
let $config = {  
  ...  
  
  keybindings: [  
    {  
      name: completion_menu  
      modifier: control  
      keycode: char_t  
      mode: emacs  
      event: { send: menu name: completion_menu }  
    }  
  ]  
  
  ...  
}
```

After loading this new `config.nu`, your new keybinding (`Ctrl + t`) will open the completion command.

Each keybinding requires the next elements:

- **name:** Unique name for your keybinding for easy reference in `$config.keybindings`
- **modifier:** A key modifier for the keybinding. The options are:
  - none
  - control
  - alt
  - shift
  - control | alt
  - control | alt | shift
- **keycode:** This represent the key to be pressed
- **mode:** `emacs`, `vi_insert`, `vi_normal` (a single string or a list. e.g. `[vi_insert vi_normal]`)
- **event:** The type of event that is going to be sent by the keybinding. The options are:
  - send

- edit
- until

**::: tip All of the available modifiers, keycodes and events can be found**

**:: tip** The keybindings added to `vi_insert` mode will be available when the line editor is in insert mode (when you can write text), and the keybindings marked with `vi_normal` mode will be available when in normal (when the cursor moves using h, j, k or l) **:::**

The event section of the keybinding entry is where the actions to be performed are defined. In this field you can use either a record or a list of records. Something like this

```
...
event: { send: Enter }
...
```

or

```
...
event: [
  { edit: Clear }
  { send: Enter }
]
...
```

The first keybinding example shown in this page follows the first case; a single event is sent to the engine.

The next keybinding is an example of a series of events sent to the engine. It first clears the prompt, inserts a string and then enters that value

```
let $config = {
  ...

  keybindings: [
    {
      name: change_dir_with_fzf
      modifier: CONTROL
      keycode: Char_t
      mode: emacs
      event: [
```

```
        { edit: Clear }
        { edit: InsertString,
          value: "cd (ls | where type == dir | each {
|it| $it.name} | str collect (char nl) | fzf | decode utf-
8 | str trim)"
        }
      { send: Enter }
    ]
  }
  ...
}
```

One disadvantage of the previous keybinding is the fact that the inserted text will be processed by the validator and saved in the history, making the keybinding a bit slow and populating the command history with the same command. For that reason there is the `executehostcommand` type of event. The next example does the same as the previous one in a simpler way, sending a single event to the engine

```
let $config = {
  ...

  keybindings: [
    {
      name: change_dir_with_fzf
      modifier: CONTROL
      keycode: Char_y
      mode: emacs
      event: {
        send: executehostcommand,
        cmd: "cd (ls | where type == dir | each { |it|
$it.name} | str collect (char nl) | fzf | decode utf-8
| str trim)"
      }
    }
  ]
  ...
}
```

```
}
```

Before we continue you must have noticed that the syntax changes for edits and sends, and for that reason it is important to explain them a bit more. A **send** is all the **Reedline** events that can be processed by the engine and an **edit** are all the **EditCommands** that can be processed by the engine.

## Send type

To find all the available options for **send** you can use

```
keybindings list | where type == events
```

And the syntax for **send** events is the next one

```
...
  event: { send: <NAME OF EVENT FROM LIST> }
...
```

::: tip You can write the name of the events with capital letters. The keybinding parser is case insensitive :::

There are two exceptions to this rule: the **Menu** and **ExecuteHostCommand**. Those two events require an extra field to be complete. The **Menu** needs the name of the menu to be activated (`completion_menu` or `history_menu`)

```
...
  event: {
    send: menu
    name: completion_menu
  }
...
```

and the **ExecuteHostCommand** requires a valid command that will be sent to the engine

```
...
  event: {
    send: executehostcommand
    cmd: "cd ~"
  }
```

```
...
```

It is worth mentioning that in the events list you will also see `Edit([])`, `Multiple([])` and `UntilFound([])`. These options are not available for the parser since they are constructed based on the keybinding definition. For example, a `Multiple([])` event is built for you when defining a list of records in the keybinding's event. An `Edit([])` event is the same as the `edit` type that was mentioned. And the `UntilFound([])` event is the same as the `until` type mentioned before.

## Edit type

The `edit` type is the simplification of the `Edit([])` event. The `event` type simplifies defining complex editing events for the keybindings. To list the available options you can use the next command

```
keybindings list | where type == edits
```

The usual syntax for an `edit` is the next one

```
...
  event: { edit: <NAME OF EDIT FROM LIST> }
...
```

The syntax for the edits in the list that have a `()` changes a little bit. Since those edits require an extra value to be fully defined. For example, if we would like to insert a string where the prompt is located, then you will have to use

```
...
  event: {
    edit: insertstring
    value: "MY NEW STRING"
  }
...
```

or say you want to move right until the first `S`

```
...
  event: {
    edit: moverightuntil
    value: "S"
```

```
}
...
```

As you can see, these two types will allow you to construct any type of keybinding that you require

## Until type

To complete this keybinding tour we need to discuss the `until` type for event. As you have seen so far, you can send a single event or a list of events. And as we have seen, when a list of events is sent, each and every one of them is processed.

However, there may be cases when you want to assign different events to the same keybinding. This is especially useful with Nushell menus. For example, say you still want to activate your completion menu with `Ctrl + t` but you also want to move to the next element in the menu once it is activated using the same keybinding.

For these cases, we have the `until` keyword. The events listed inside the `until` event will be processed one by one with the difference that as soon as one is successful, the event processing is stopped.

The next keybinding represents this case.

```
let $config = {
  ...

  keybindings: [
    {
      name: completion_menu
      modifier: control
      keycode: char_t
      mode: emacs
      event: {
        until: [
          { send: menu name: completion_menu }
          { send: menunext }
        ]
      }
    }
  ]
}
```

```
}
```

The previous keybinding will first try to open a completion menu. If the menu is not active, it will activate it and send a success signal. If the keybinding is pressed again, since there is an active menu, then the next event it will send is `MenuNext`, which means that it will move the selector to the next element in the menu.

As you can see the `until` keyword allows us to define two events for the same keybinding. At the moment of this writing, only the `Menu` events allow this type of layering. The other non menu event types will always return a success value, meaning that the `until` event will stop as soon as it reaches the command.

For example, the next keybinding will always send a `down` because that event is always successful

```
let $config = {  
  ...  
  
  keybindings: [  
    {  
      name: completion_menu  
      modifier: control  
      keycode: char_t  
      mode: emacs  
      event: {  
        until: [  
          { send: down }  
          { send: menu name: completion_menu }  
          { send: menunext }  
        ]  
      }  
    ]  
  }  
  ...  
}
```

## Removing a default keybinding

If you want to remove a certain default keybinding without replacing it with a different action, you can set `event: null`.

e.g. to disable screen clearing with **Ctrl + l** for all edit modes

```
let $config = {  
    ...  
  
    keybindings: [  
        {  
            modifier: control  
            keycode: char_l  
            mode: [emacs, vi_normal, vi_insert]  
            event: null  
        }  
    ]  
  
    ...  
}
```

## Troubleshooting keybinding problems

Your terminal environment may not always propagate your key combinations on to nushell the way you expect it to. You can use the command **keybindings listen** to figure out if certain keypresses are actually received by nushell, and how.

## Menus

Thanks to Reedline, Nushell has menus that can help you with your day to day shell scripting. Next we present the default menus that are always available when using Nushell

### Help menu

The help menu is there to ease your transition into Nushell. Say you are putting together an amazing pipeline and then you forgot the internal command that would reverse a string for you. Instead of deleting your pipe, you can activate the help menu with **ctr+q**. Once active just type keywords for the command you are looking for and the menu will show you commands that match your input. The matching is done on the name of the commands or the commands description.

To navigate the menu you can select the next element by using **tab**, you can scroll the description by pressing left or right and you can even paste into the line the available command examples.

The help menu can be configured by modifying the next parameters

```
let $config = {
  ...

  menus = [
    ...
    {
      name: help_menu
      only_buffer_difference: true # Search is done on
the text written after activating the menu
      marker: "? "                # Indicator that appears
with the menu is active
      type: {
        layout: description      # Type of menu
        columns: 4                # Number of columns
where the options are displayed
        col_width: 20            # Optional value.
If missing all the screen width is used to calculate column
width
        col_padding: 2          # Padding between
columns
        selection_rows: 4        # Number of rows allowed
to display found options
        description_rows: 10     # Number of rows allowed
to display command description
      }
      style: {
        text: green              # Text style
        selected_text: green_reverse # Text style
for selected option
        description_text: yellow  # Text style
for description
      }
    }
    ...
  ]
  ...
}
```

## Completion menu

The completion menu is a context sensitive menu that will present suggestions based on the status of the prompt. These suggestions can range from path suggestions to command alternatives. While writing a command, you can activate the menu to see available flags for an internal command. Also, if you have defined your custom completions for external commands, these will appear in the menu as well.

The completion menu by default is accessed by pressing **tab** and it can be configured by modifying these values from the config object:

```
let $config = {
  ...

  menus = [
    ...
    {
      name: completion_menu
      only_buffer_difference: false # Search is done
on the text written after activating the menu
      marker: "| "                  # Indicator that
appears with the menu is active
      type: {
        layout: columnar           # Type of menu
        columns: 4                 # Number of columns
where the options are displayed
        col_width: 20              # Optional value.
If missing all the screen width is used to calculate column
width
        col_padding: 2            # Padding between
columns
      }
      style: {
        text: green                # Text style
        selected_text: green_reverse # Text style
for selected option
        description_text: yellow   # Text style
for description
      }
    }
  ]
}
```

```
    }  
    ...  
  ]  
  ...
```

By modifying these parameters you can customize the layout of your menu to your liking.

## History menu

The history menu is a handy way to access the editor history. When activating the menu (default **Ctrl+x**) the command history is presented in reverse chronological order, making it extremely easy to select a previous command.

The history menu can be configured by modifying these values from the config object:

```
let $config = {  
  ...  
  
  menus = [  
    ...  
    {  
      name: help_menu  
      only_buffer_difference: true # Search is done on  
the text written after activating the menu  
      marker: "? "                # Indicator that appears  
with the menu is active  
      type: {  
        layout: list              # Type of menu  
        page_size: 10            # Number of entries  
that will presented when activating the menu  
      }  
      style: {  
        text: green               # Text style  
        selected_text: green_reverse # Text style  
for selected option  
        description_text: yellow   # Text style  
for description  
      }  
    }  
  ]  
}
```

```
...
]
...
```

When the history menu is activated, it pulls `page_size` records from the history and presents them in the menu. If there is space in the terminal, when you press `Ctrl+x` again the menu will pull the same number of records and append them to the current page. If it isn't possible to present all the pulled records, the menu will create a new page. The pages can be navigated by pressing `Ctrl+z` to go to previous page or `Ctrl+x` to go to next page.

## Searching the history

To search in your history you can start typing key words for the command you are looking for. Once the menu is activated, anything that you type will be replaced by the selected command from your history. for example, say that you have already typed this

```
let a = ()
```

you can place the cursor inside the `()` and activate the menu. You can filter the history by typing key words and as soon as you select an entry, the typed words will be replaced

```
let a = (ls | where size > 10MiB)
```

## Menu quick selection

Another nice feature of the menu is the ability to quick select something from it. Say you have activated your menu and it looks like this

```
>
0: ls | where size > 10MiB
1: ls | where size > 20MiB
2: ls | where size > 30MiB
3: ls | where size > 40MiB
```

Instead of pressing down to select the fourth entry, you can type `!3` and press enter. This will insert the selected text in the prompt position, saving you time scrolling down the menu.

History search and quick selection can be used together. You can activate the menu, do a quick search, and then quick select using the quick selection character.

## User defined menus

In case you find that the default menus are not enough for you and you have the need to create your own menu, Nushell can help you with that.

In order to add a new menu that fulfills your needs, you can use one of the default layouts as a template. The templates available in nushell are columnar, list or description.

The columnar menu will show you data in a columnar fashion adjusting the column number based on the size of the text displayed in your columns.

The list type of menu will always display suggestions as a list, giving you the option to select values using ! plus number combination.

The description type will give you more space to display a description for some values, together with extra information that could be inserted into the buffer.

Let's say we want to create a menu that displays all the variables created during your session, we are going to call it `vars_menu`. This menu will use a list layout (layout: list). To search for values, we want to use only the things that are written after the menu has been activated (only\_buffer\_difference: true).

With that in mind, the desired menu would look like this

```
let $config = {
  ...

  menus = [
    ...
    {
      name: vars_menu
      only_buffer_difference: true
      marker: "# "
      type: {
        layout: list
        page_size: 10
      }
      style: {
```

```

        text: green
        selected_text: green_reverse
        description_text: yellow
    }
    source: { |buffer, position|
        $nu.scope.vars
        | where name =~ $buffer
        | sort-by name
        | each { |it| {value: $it.name description:
$it.type} }
    }
}
...
]
...

```

As you can see, the new menu is identical to the `history_menu` previously described. The only huge difference is the new field called `source`. The `source` field is a nushell definition of the values you want to display in the menu. For this menu we are extracting the data from `$nu.scope.vars` and we are using it to create records that will be used to populate the menu.

The required structure for the record is the next one

```

{
  value:           # The value that will be inserted in the
buffer
  description: # Optional. Description that will be display
with the selected value
  span: {         # Optional. Span indicating what section
of the string will be replaced by the value
    start:
    end:
  }
  extra: [string] # Optional. A list of strings that will
be displayed with the selected value. Only works with a
description menu
}

```

For the menu to display something, at least the `value` field has to be present in the resulting record.

In order to make the menu interactive, these two variables are available in the block: `$buffer` and `$position`. The `$buffer` contains the value captured by the menu, when the option `only_buffer_difference` is true, `$buffer` is the text written after the menu was activated. If `only_buffer_difference` is false, `$buffer` is all the string in line. The `$position` variable can be used to create replacement spans based on the idea you had for your menu. The value of `$position` changes based on whether `only_buffer_difference` is true or false. When true, `$position` is the starting position in the string where text was inserted after the menu was activated. When the value is false, `$position` indicates the actual cursor position.

Using this information, you can design your menu to present the information you require and to replace that value in the location you need it. The only thing extra that you need to play with your menu is to define a keybinding that will activate your brand new menu.

## Menu keybindings

In case you want to change the default way both menus are activated, you can change that by defining new keybindings. For example, the next two keybindings assign the completion and history menu to `Ctrl+t` and `Ctrl+y` respectively

```
let $config = {
  ...

  keybindings: [
    {
      name: completion_menu
      modifier: control
      keycode: char_t
      mode: [vi_insert vi_normal]
      event: {
        until: [
          { send: menu name: completion_menu }
          { send: menupagenext }
        ]
      }
    }
  ]
  {
    name: history_menu
```

```
modifier: control
keycode: char_y
mode: [vi_insert vi_normal]
event: {
  until: [
    { send: menu name: history_menu }
    { send: menupagenext }
  ]
}
]
```

...

```
}
```

# Chapter 24

## Externs

Calling external commands is a fundamental part of using Nushell as a shell (and often using Nushell as a language). There's a problem, though, commands outside of Nushell means that Nushell can't help with finding errors in the call, or completions, or syntax highlighting.

This is where **extern** comes in. The **extern** keyword allows you to write a full signature for the command that lives outside of Nushell so that you get all the benefits above. If you take a look at the default config, you'll notice that there are a few extern calls in there. Here's one of them:

```
export extern "git push" [  
  remote?: string@"nu-complete git remotes", # the name  
of the remote  
  refspec?: string@"nu-complete git branches"# the branch

addresses only
    --ipv6(-6)                               # use IPv6
addresses only
]
```

You'll notice this gives you all the same descriptive syntax that internal commands do, letting you describe flags, short flags, positional

parameters, types, and more.

## Types and custom completions

In the above example, you'll notice some types are followed by `@` followed by the name of a command. We talk more about **custom completions** in their own section.

Both the type (or shape) of the argument and the custom completion tell Nushell about how to complete values for that flag or position. For example, setting a shape to `path` allows Nushell to complete the value to a filepath for you. Using the `@` with a custom completion overrides this default behavior, letting the custom completion give you full completion list.

## Limitations

There are a few limitations to the current **extern** syntax. In Nushell, flags and positional arguments are very flexible: flags can precede positional arguments, flags can be mixed into positional arguments, and flags can follow positional arguments. Many external commands are not this flexible. There is not yet a way to require a particular ordering of flags and positional arguments to the style required by the external.

The second limitation is that some externals require flags to be passed using `=` to separate the flag and the value. In Nushell, the `=` is a convenient optional syntax and there's currently no way to required its use.

# Chapter 25

## Custom completions

Custom completions allow you to mix together two features of Nushell: custom commands and completions. With them, you're able to create commands that handle the completions for positional parameters and flag parameters. These custom completions work both custom commands and **known external, or extern, commands**.

There are two parts to a custom command: the command that handles a completion and attaching this command to the type of another command using `@`.

### Example custom completion

Let's look at an example:

```
> def animals [] { ["cat", "dog", "eel" ] }
> def my-command [animal: string@animals] { print $animal
}
>| my-command
cat                dog                eel
```

In the first line, we create a custom command that will return a list of three different animals. These are the values we'd like to use in the completion. Once we've created this command, we can now use it to provide completions for other custom commands and **externs**.

In the second line, we use `string@animals`. This tells Nushell two things: the shape of the argument for type-checking and the custom completion to use if the user wants to complete values at that position.

On the third line, we type the name of our custom command `my-command` followed by hitting space and then the `<tab>` key. This brings up our completions. Custom completions work the same as other completions in the system, allowing you to type `e` followed by the `<tab>` key and get “eel” automatically completed.

## Modules and custom completions

You may prefer to keep your custom completions away from the public API for your code. For this, you can combine modules and custom completions.

Let’s take the example above and put it into a module:

```
module commands {
  def animals [] {
    ["cat", "dog", "eel" ]
  }

  export def my-command [animal: string@animals] {
    print $animal
  }
}
```

In our module, we’ve chosen to export only the custom command `my-command` but not the custom completion `animals`. This allows users of this module to call the command, and even use the custom completion logic, without having access the the custom completion. This keeps the API cleaner, while still offering all the same benefits.

This is possible because custom completion tags using `@` are locked-in as the command is first parsed.

## Custom completion and `extern`

A powerful combination is adding custom completions to **known extern commands**. These work the same way as adding a custom completion to a custom command: by creating the custom completion and then attaching it with a `@` to the type of one of the positional or flag arguments of the `extern`.

If you look closely at the examples in the default config, you’ll see this:

```
export extern "git push" [  
    remote?: string@"nu-complete git remotes", # the name  
    of the remote  
    refspec?: string@"nu-complete git branches"# the branch  
    / refspec  
    ...  
]
```

Custom completions will serve the same role in this example as in the previous examples. The examples above call into two different custom completions, based on the position the user is currently in.

## Chapter 26

# Coloring and theming in Nu

Many parts of Nushell's interface can have their color customized. All of these can be set in the `config.nu` configuration file. If you see the hash/hashtag/pound mark `#` in the config file it means the text after it is commented out.

1. table borders
2. primitive values
3. shapes (this is the command line syntax)
4. prompt
5. `LS_COLORS`

### Table borders

Table borders are controlled by the `table_mode` setting in `config.nu`. Here is an example:

```
> let $config = {  
    table_mode: rounded  
}
```

Here are the current options for `table_mode`:

- rounded # of course, this is the best one :)
- basic
- compact
- compact\_double
- light
- thin
- with\_love
- reinforced
- heavy
- none
- other

## Color symbologies

- r - normal color red's abbreviation
- rb - normal color red's abbreviation with bold attribute
- red - normal color red
- red\_bold - normal color red with bold attribute
- "#ff0000" - "#hex" format foreground color red (quotes are required)
- { fg: "#ff0000" bg: "#0000ff" attr: b } - "full #hex" format foreground red in "#hex" format with a background of blue in "#hex" format with an attribute of bold abbreviated.

**attributes**

code	meaning
l	blink
b	bold
d	dimmed
h	hidden
i	italic
r	reverse
s	strikethrough
u	underline
n	nothing
	defaults to nothing

**normal colors and abbreviations**

code	name
g	green
gb	green_bold
gu	green_underline
gi	green_italic
gd	green_dimmed
gr	green_reverse
gbl	green_blink
gst	green_strike
lg	light_green
lgb	light_green_bold
lgu	light_green_underline
lgi	light_green_italic
lgd	light_green_dimmed
lgr	light_green_reverse
lgbl	light_green_blink
lgst	light_green_strike
r	red
rb	red_bold
ru	red_underline
ri	red_italic
rd	red_dimmed
rr	red_reverse
rbl	red_blink
rst	red_strike
lr	light_red
lrb	light_red_bold
lru	light_red_underline
lri	light_red_italic
lrd	light_red_dimmed
lrr	light_red_reverse
lrbl	light_red_blink
lrst	light_red_strike
u	blue
ub	blue_bold
uu	blue_underline
ui	blue_italic
ud	blue_dimmed
ur	blue_reverse
ubl	blue_blink
ust	blue_strike
lu	light_blue
lub	light_blue_bold
luu	light_blue_underline

## "#hex" format

The “#hex” format is one way you typically see colors represented. It’s simply the # character followed by 6 characters. The first two are for **red**, the second two are for **green**, and the third two are for **blue**. It’s important that this string be surrounded in quotes, otherwise Nushell thinks it’s a commented out string.

Example: The primary **red** color is "#ff0000" or "#FF0000". Upper and lower case in letters shouldn’t make a difference.

This "#hex" format allows us to specify 24-bit truecolor tones to different parts of Nushell.

## full "#hex" format

The full "#hex" format is a take on the "#hex" format but allows one to specify the foreground, background, and attributes in one line.

Example: { fg: "#ff0000" bg: "#0000ff" attr: b }

- foreground of red in “#hex” format
- background of blue in “#hex” format
- attribute of bold abbreviated

## Primitive values

Primitive values are things like **int** and **string**. Primitive values and shapes can be set with a variety of color symbologies seen above.

This is the current list of primitives. Not all of these are configurable. The configurable ones are marked with \*.

primitive	default color	configurable
any		
binary	Color::White.normal()	*
block	Color::White.normal()	*
bool	Color::White.normal()	*
cellpath	Color::White.normal()	*
condition		
custom		
date	Color::White.normal()	*
duration	Color::White.normal()	*
expression		
filesize	Color::White.normal()	*
float	Color::White.normal()	*
glob		
import		
int	Color::White.normal()	*
list	Color::White.normal()	*
nothing	Color::White.normal()	*
number		
operator		
path		
range	Color::White.normal()	*
record	Color::White.normal()	*
signature		
string	Color::White.normal()	*
table		
var		
vardecl		
variable		

**special “primitives” (not really primitives but they exist solely for coloring)**

primitive	default color	configurable
leading_	Color::Rgb(128, 128,	*
trailing_space_bg	128))	
header	Color::Green.bold()	*
empty	Color::Blue.normal()	*
row_index	Color::Green.bold()	*
hints	Color::DarkGray.normal()	*

Here’s a small example of changing some of these values.

```
> let config = {
  color_config: {
    separator: purple
    leading_trailing_space_bg: "#ffffff"
    header: gb
    date: wd
    filesize: c
    row_index: cb
    bool: red
    int: green
    duration: blue_bold
    range: purple
    float: red
    string: white
    nothing: red
    binary: red
    cellpath: cyan
    hints: dark_gray
  }
}
```

Here's another small example using multiple color syntaxes with some comments.

```
> let config = {
  color_config: {
    separator: "#88b719" # this sets only the foreground
color like PR #486
    leading_trailing_space_bg: white # this sets only
the foreground color in the original style
    header: { # this is like PR #489
      fg: "#B01455", # note, quotes are required on the
values with hex colors
      bg: "#ffb900",# note, commas are not required,
it could also be all on one line
      attr: bli # note, there are no quotes around this
value. it works with or without quotes
    }
    date: "#75507B"
    filesize: "#729fcf"
```

```

        row_index: { # note, that this is another way to
set only the foreground, no need to specify bg and attr
        fg: "#e50914"
    }
}

```

## Shape values

As mentioned above, **shape** is a term used to indicate the syntax coloring.

Here's the current list of flat shapes.

shape	default style	configurable
shape_block	fg(Color::Blue).bold()	*
shape_bool	fg(Color::LightCyan)	*
shape_custom	bold()	*
shape_external	fg(Color::Cyan)	*
shape_externalarg	fg(Color::Green).bold()	*
shape_filepath	fg(Color::Cyan)	*
shape_flag	fg(Color::Blue).bold()	*
shape_float	fg(Color::Purple).bold()	*
shape_garbage	fg(Color::White).on(Color::Red).bold()	
shape_globpattern	fg(Color::Cyan).bold()	*
shape_int	fg(Color::Purple).bold()	*
shape_-	fg(Color::Cyan).bold()	*
internalcall		
shape_list	fg(Color::Cyan).bold()	*
shape_literal	fg(Color::Blue)	*
shape_nothing	fg(Color::LightCyan)	*
shape_operator	fg(Color::Yellow)	*
shape_range	fg(Color::Yellow).bold()	*
shape_record	fg(Color::Cyan).bold()	*
shape_signature	fg(Color::Green).bold()	*
shape_string	fg(Color::Green)	*
shape_string_	fg(Color::Cyan).bold()	*
interpolation		
shape_table	fg(Color::Blue).bold()	*
shape_variable	fg(Color::Purple)	*

Here's a small example of how to apply color to these items. Anything not specified will receive the default color.

```
> let $config = {
    color_config: {
        shape_garbage: { fg: "#FFFFFF" bg: "#FF0000" attr:
b}

        shape_bool: green
        shape_int: { fg: "#0000ff" attr: b}
    }
}
```

## Prompt configuration and coloring

The Nushell prompt is configurable through these environment variables:

- `PROMPT_COMMAND`: Code to execute for setting up the prompt (block)
- `PROMPT_COMMAND_RIGHT`: Code to execute for setting up the *RIGHT* prompt (block) (see `oh-my.nu` in `nu_scripts`)
- `PROMPT_INDICATOR = " "`: The indicator printed after the prompt (by default “>”-like Unicode symbol)
- `PROMPT_INDICATOR_VI_INSERT = “: ”`
- `PROMPT_INDICATOR_VI_NORMAL = “v ”`
- `PROMPT_MULTILINE_INDICATOR = “::: ”`

Example: For a simple prompt one could do this. Note that `PROMPT_COMMAND` requires a **block** whereas the others require a **string**.

```
> let-env PROMPT_COMMAND = { build-string (date now | date
format '%m/%d/%Y %I:%M:%S%.3f') ': ' (pwd | path basename)
}
```

If you don't like the default `PROMPT_INDICATOR` you could change it like this.

```
> let-env PROMPT_INDICATOR = "> "
```

Coloring of the prompt is controlled by the `block` in `PROMPT_COMMAND` where you can write your own custom prompt. We've written a slightly fancy one that has git statuses located in the [nu\\_scripts repo](#)<sup>1</sup>.

## LS\_COLORS colors for the `ls` command

Nushell will respect and use the `LS_COLORS` environment variable setting on Mac, Linux, and Windows. This setting allows you to define the color of file types when you do a `ls`. For instance, you can make directories one color, `__md` markdown files another color, `__toml` files yet another color, etc. There are a variety of ways to color your file types.

There's an exhaustive list [here](#)<sup>2</sup>, which is overkill, but gives you an rudimentary understanding of how to create a `ls_colors` file that `dircolors` can turn into a `LS_COLORS` environment variable.

[This](#)<sup>3</sup> is a pretty good introduction to `LS_COLORS`. I'm sure you can find many more tutorials on the web.

I like the `vivid` application and currently have it configured in my `config.nu` like this. You can find `vivid` [here](#)<sup>4</sup>.

```
let-env LS_COLORS = (vivid generate molokai | str trim)
```

If `LS_COLORS` is not set, nushell will default to a builtin `LS_COLORS` setting, based on 8-bit (extended) ANSI colors.

## Theming

Theming combines all the coloring above. Here's a quick example of one we put together quickly to demonstrate the ability to theme. This is a spin on the `base16` themes that we see so widespread on the web.

The key to making theming work is to make sure you specify all themes and colors you're going to use in the `config.nu` file *before* you declare the `let config =` line.

```
# let's define some colors

let base00 = "#181818" # Default Background
```

---

<sup>1</sup>[https://github.com/nushell/nu\\_scripts/blob/main/engine-q/prompt/oh-my.nu](https://github.com/nushell/nu_scripts/blob/main/engine-q/prompt/oh-my.nu)

<sup>2</sup>[https://github.com/trapd00r/LS\\_COLORS](https://github.com/trapd00r/LS_COLORS)

<sup>3</sup><https://www.linuxhowto.net/how-to-set-colors-for-ls-command/>

<sup>4</sup><https://github.com/sharkdp/vivid>

```
let base01 = "#282828" # Lighter Background (Used for status
bars, line number and folding marks)
let base02 = "#383838" # Selection Background
let base03 = "#585858" # Comments, Invisibles, Line Highlighting
let base04 = "#b8b8b8" # Dark Foreground (Used for status
bars)
let base05 = "#d8d8d8" # Default Foreground, Caret, Delimiters,
Operators
let base06 = "#e8e8e8" # Light Foreground (Not often used)

let base07 = "#f8f8f8" # Light Background (Not often used)

let base08 = "#ab4642" # Variables, XML Tags, Markup Link
Text, Markup Lists, Diff Deleted
let base09 = "#dc9656" # Integers, Boolean, Constants,
XML Attributes, Markup Link Url
let base0a = "#f7ca88" # Classes, Markup Bold, Search Text
Background
let base0b = "#a1b56c" # Strings, Inherited Class, Markup
Code, Diff Inserted
let base0c = "#86c1b9" # Support, Regular Expressions,
Escape Characters, Markup Quotes
let base0d = "#7cafc2" # Functions, Methods, Attribute
IDs, Headings
let base0e = "#ba8baf" # Keywords, Storage, Selector, Markup
Italic, Diff Changed
let base0f = "#a16946" # Deprecated, Opening/Closing Embedded
Language Tags, e.g. <?php ?>

# we're creating a theme here that uses the colors we defined
above.

let base16_theme = {
  separator: $base03
  leading_trailing_space_bg: $base04
  header: $base0b
  date: $base0e
  filesize: $base0d
  row_index: $base0c
  bool: $base08
```

```
int: $base0b
duration: $base08
range: $base08
float: $base08
string: $base04
nothing: $base08
binary: $base08
cellpath: $base08
hints: dark_gray

# shape_garbage: { fg: $base07 bg: $base08 attr: b}
# base16 white on red
# but i like the regular white on red for parse errors
shape_garbage: { fg: "#FFFFFF" bg: "#FF0000" attr:
b}
  shape_bool: $base0d
  shape_int: { fg: $base0e attr: b}
  shape_float: { fg: $base0e attr: b}
  shape_range: { fg: $base0a attr: b}
  shape_internalcall: { fg: $base0c attr: b}
  shape_external: $base0c
  shape_externalarg: { fg: $base0b attr: b}
  shape_literal: $base0d
  shape_operator: $base0a
  shape_signature: { fg: $base0b attr: b}
  shape_string: $base0b
  shape_filepath: $base0d
  shape_globpattern: { fg: $base0d attr: b}
  shape_variable: $base0e
  shape_flag: { fg: $base0d attr: b}
  shape_custom: {attr: b}
}

# now let's apply our regular config settings but also
# apply the "color_config:" theme that we specified above.

let config = {
  filesize_metric: true
  table_mode: rounded # basic, compact, compact_double,
```

```
light, thin, with_love, rounded, reinforced, heavy, none,
other
  use_ls_colors: true
  color_config: $base16_theme # <-- this is the theme
  use_grid_icons: true
  footer_mode: always #always, never, number_of_rows, auto
  animate_prompt: false
  float_precision: 2
  use_ansi_coloring: true
  filesize_format: "b" # b, kb, kib, mb, mib, gb, gib,
tb, tib, pb, pib, eb, eib, zb, zib, auto
  edit_mode: emacs # vi
  max_history_size: 10000
  log_level: error
}
```

if you want to go full-tilt on theming, you'll want to theme all the items I mentioned at the very beginning, including LS\_COLORS, and the prompt. Good luck!

## Chapter 27

# Coming from Bash

If you're coming from **Git Bash** on Windows, then the external commands you're used to (**bash**, **grep**, etc) will not be available in **nu** by default (unless you had explicitly made them available in the Windows Path environment variable). To make these commands available in **nu** as well, add the following line to your **config.nu** with either **append** or **prepend**.

```
let-env Path = ($env.Path | prepend 'C:\Program Files\Git\usr\bin')
```

Note: this table assumes Nu 0.14.1 or later.

Bash	Nu	Task
<code>ls</code>	<code>ls</code>	Lists the files in the current directory
<code>ls &lt;dir&gt;</code>	<code>ls &lt;dir&gt;</code>	Lists the files in the given directory
<code>ls pattern*</code>	<code>ls pattern*</code>	Lists files that match a given pattern
<code>ls -la</code>	<code>ls --long --all</code> or <code>ls -la</code>	List files with all available information, including hidden files
<code>ls -d */</code>	<code>'ls</code>	where type == dir'
<code>find . -name *.rs</code>	<code>ls **/*.rs</code>	Find recursively all files that match a given pattern
<code>'find . -name Makefile</code>	<code>xargs vim'</code>	<code>'ls **/Makefile</code>
<code>cd &lt;directory&gt;</code>	<code>cd &lt;directory&gt;</code>	Change to the given directory
<code>cd</code>	<code>cd</code>	Change to the home directory
<code>cd -</code>	<code>cd -</code>	Change to the previous directory
<code>mkdir &lt;path&gt;</code>	<code>mkdir &lt;path&gt;</code>	Creates the given path
<code>mkdir -p &lt;path&gt;</code>	<code>mkdir &lt;path&gt;</code>	Creates the given path, creating parents as necessary
<code>touch test.txt</code>	<code>touch test.txt</code>	Create a file
<code>&gt; &lt;path&gt;</code>	<code>'</code>	<code>save --raw &lt;path&gt;'</code>
<code>&gt;&gt; &lt;path&gt;</code>	<code>&lt;not yet possible&gt;</code>	Append string to a file
<code>cat &lt;path&gt;</code>	<code>open --raw &lt;path&gt;</code>	Display the contents of the given file
	<code>open &lt;path&gt;</code>	Read a file as structured data
<code>mv &lt;source&gt;</code>	<code>mv &lt;source&gt;</code>	Move file to new location
<code>&lt;dest&gt;</code>	<code>&lt;dest&gt;</code>	
<code>cp &lt;source&gt;</code>	<code>cp &lt;source&gt;</code>	Copy file to new location
<code>&lt;dest&gt;</code>	<code>&lt;dest&gt;</code>	
<code>cp -r &lt;source&gt;</code>	<code>cp -r &lt;source&gt;</code>	Copy directory to a new location, recursively
<code>&lt;dest&gt;</code>	<code>&lt;dest&gt;</code>	
<code>rm &lt;path&gt;</code>	<code>rm &lt;path&gt;</code>	Remove the given file

## Chapter 28

# Nu map from other shells and domain specific languages

The idea behind this table is to help you understand how Nu built-ins and plug-ins relate to other known shells and domain specific languages. We've tried to produce a map of all the Nu commands and what their equivalents are in other languages. Contributions are welcome.

Note: this table assumes Nu 0.43 or later.

Nushell	SQL	.Net LINQ (C#)	PowerShell (without external modules)	Bash
alias	-	-	alias	alias
append	-	Append	-Append	
args	-	-		
autoview	-	-		
math avg	avg	Average	Measure-Object, measure	
calc, <math expression>	math operators	Aggregate, Average, Count, Max, Min, Sum		bc
cd	-	-	Set-Location, cd	cd
clear	-	-	Clear-Host	clear
compact config	-	-	\$Profile	vi .bashrc, .profile
count	count	Count	Measure-Object, measure	wc
cp	-	-	Copy-Item, cp, copy	cp
date	NOW() / getdate()	DateTime class	Get-Date	date
debug				
default				
drop				
du	-	-		du
each	cursor		ForEach-Object, foreach, for	
echo	print, union all	-	Write-Output, write	echo

	or	or		-Or,	-o,

# Chapter 32

## Dataframes

::: tip The dataframe commands are available from version 0.33.1 onwards :::

As we have seen so far, Nushell makes working with data its main priority. **Lists** and **Tables** are there to help you cycle through values in order to perform multiple operations or find data in a breeze. However, there are certain operations where a row-based data layout is not the most efficient way to process data, especially when working with extremely large files. Operations like group-by or join using large datasets can be costly memory-wise, and may lead to large computation times if they are not done using the appropriate data format.

For this reason, the **DataFrame** structure was introduced to Nushell. A **DataFrame** stores its data in a columnar format using as its base the **Apache Arrow**<sup>1</sup> specification, and uses **Polars**<sup>2</sup> as the motor for performing extremely **fast columnar operations**<sup>3</sup>.

You may be wondering now how fast this combo could be, and how could it make working with data easier and more reliable. For this reason, let's start this page by presenting benchmarks on common operations that are done when processing data.

---

<sup>1</sup><https://arrow.apache.org/>

<sup>2</sup><https://github.com/pola-rs/polars>

<sup>3</sup><https://h2oai.github.io/db-benchmark/>

## Benchmark comparisons

For this little benchmark exercise we will be comparing native Nushell commands, dataframe Nushell commands and **Python Pandas**<sup>4</sup> commands. For the time being don't pay too much attention to the **dataframe** commands. They will be explained in later sections of this page.

*System Details: The benchmarks presented in this section were run using a machine with a processor Intel(R) Core(TM) i7-10710U (CPU @1.10GHz 1.61 GHz) and 16 gb of RAM.*

*All examples were run on Nushell version 0.33.1.*

### File information

The file that we will be using for the benchmarks is the **New Zealand business demography**<sup>5</sup> dataset. Feel free to download it if you want to follow these tests.

The dataset has 5 columns and 5,429,252 rows. We can check that by using the **dfr list** command:

```
> let df = (dfr open .\Data7602DescendingYearOrder.csv)

> dfr list

#   name      rows    columns
0   $df      5429252    5
```

We can have a look at the first lines of the file using **dfr first**:

```
> $df | dfr first

#   anzsic06   Area    year   geo_count   ec_count
```

<sup>4</sup><https://pandas.pydata.org/>

<sup>5</sup><https://www.stats.govt.nz/assets/Uploads/New-Zealand-business-demography-statistics/New-Zealand-business-demography-statistics-At-February-2020/Download-data/Geographic-units-by-industry-and-statistical-area-2000-2020-descending-order.zip>

0	A	A100100	2000	96	130
1	A	A100200	2000	198	110
2	A	A100300	2000	42	25
3	A	A100400	2000	66	40
4	A	A100500	2000	63	40

...and finally, we can get an idea of the inferred datatypes:

```
> $df | dfr dtypes

#      column      dtype
0  anzsic06      str
1   Area        str
2   year        i64
3 geo_count    i64
4  ec_count    i64
```

## Loading the file

Let's start by comparing loading times between the various methods. First, we will load the data using Nushell's **open** command:

```
> benchmark {open .\Data7602DescendingYearOrder.csv}

#           real time
0   30sec 479ms 614us 400ns
```

Loading the file using native Nushell functionality took 30 seconds. Not bad for loading five million records! But we can do a bit better than that.

Let's now use Pandas. We are going to use the next script to load the file:

```
import pandas as pd

df = pd.read_csv("Data7602DescendingYearOrder.csv")
```

And the benchmark for it is:

```
> benchmark {python load.py}

#           real time

0    2sec 91ms 872us 900ns
```

That is a great improvement, from 30 seconds to 2 seconds. Nicely done, Pandas!

Probably we can load the data a bit faster. This time we will use Nushell's `dfr open` command:

```
> benchmark {dfr open .\Data7602DescendingYearOrder.csv}

#           real time

0    601ms 700us 700ns
```

This time it took us 0.6 seconds. Not bad at all.

## Group-by comparison

Let's do a slightly more complex operation this time. We are going to group the data by year, and add groups using the column `geo_count`.

**Again, we are going to start with a Nushell native command.**

:: tip If you want to run this example, be aware that the next command will use a large amount of memory. This may affect the performance of your system while this is being executed. ::

```
> benchmark {  
  open .\Data7602DescendingYearOrder.csv  
  | group-by year  
  | pivot header rows  
  | upsert rows { get rows | math sum }  
  | flatten  
}  
  
#           real time  
  
0   6min 30sec 622ms 312us
```

So, six minutes to perform this aggregated operation.

Let's try the same operation in pandas:

```
import pandas as pd  
  
df = pd.read_csv("Data7602DescendingYearOrder.csv")  
res = df.groupby("year")["geo_count"].sum()  
print(res)
```

And the result from the benchmark is:

```
> benchmark {python .\load.py}  
  
#           real time  
  
0   1sec 966ms 954us 800ns
```

Not bad at all. Again, pandas managed to get it done in a fraction of the time.

To finish the comparison, let's try Nushell dataframes. We are going to put all the operations in one **nu** file, to make sure we are doing similar operations:

```
let df = (dfr open Data7602DescendingYearOrder.csv)
let res = ($df | dfr group-by year | dfr aggregate sum
| dfr select geo_count)
$res
```

and the benchmark with dataframes is:

```
> benchmark {source load.nu}

#           real time

0    557ms 658us 500ns
```

Luckily Nushell dataframes managed to halve the time again. Isn't that great?

As you can see, Nushell's **Dataframe** commands are as fast as the most common tools that exist today to do data analysis. The commands that are included in this release have the potential to become your go-to tool for doing data analysis. By composing complex Nushell pipelines, you can extract information from data in a reliable way.

## Working with Dataframes

After seeing a glimpse of the things that can be done with **Dataframe** commands, now it is time to start testing them. To begin let's create a sample CSV file that will become our sample dataframe that we will be using along with the examples. In your favorite file editor paste the next lines to create out sample csv file.

```
int_1,int_2,float_1,float_2,first,second,third,word
1,11,0.1,1.0,a,b,c,first
2,12,0.2,1.0,a,b,c,second
3,13,0.3,2.0,a,b,c,third
4,14,0.4,3.0,b,a,c,second
0,15,0.5,4.0,b,a,a,third
6,16,0.6,5.0,b,a,a,second
7,17,0.7,6.0,b,c,a,third
8,18,0.8,7.0,c,c,b,eight
```

```
9,19,0.9,8.0,c,c,b,ninth
0,10,0.0,9.0,c,c,b,ninth
```

Save the file and name it however you want to, for the sake of these examples the file will be called `test_small.csv`.

Now, to read that file as a dataframe use the `dfr open` command like this:

```
> let df = (dfr open test_small.csv)
```

**This should create the value `df` in memory which holds the data we just**

**:: tip** The command `dfrs open` can read either **csv** or **parquet** files. **:::**

To see all the dataframes that are stored in memory you can use

```
> dfr list

#   name   rows  columns
0  $df    10     8
```

As you can see, the command shows the created dataframes together with basic information about them.

And if you want to see a preview of the loaded dataframe you can send the dataframe variable to the stream

```
> $df

#   int_1  int_2  float_1  float_2  first  second
third   word
0       1    11   0.1000   1.0000   a       b
c      first
1       2    12   0.2000   1.0000   a       b
c      second
2       3    13   0.3000   2.0000   a       b
c      third
```

3	4	14	0.4000	3.0000	b	a
c	second					
4	0	15	0.5000	4.0000	b	a
a	third					
5	6	16	0.6000	5.0000	b	a
a	second					
6	7	17	0.7000	6.0000	b	c
a	third					
7	8	18	0.8000	7.0000	c	c
b	eight					
8	9	19	0.9000	8.0000	c	c
b	ninth					
9	0	10	0.0000	9.0000	c	c
b	ninth					

**With the dataframe in memory we can start doing column operations with**

:: tip If you want to see all the dataframe commands that are available you can use `help dfr ::`

## Basic aggregations

Let's start with basic aggregations on the dataframe. Let's sum all the columns that exist in `df` by using the `aggregate` command

```
> $df | dfr aggregate sum

#  int_1  int_2  float_1  float_2  first  second
third word
0      40    145    4.5000   46.0000
```

As you can see, the aggregate function computes the sum for those columns where a sum makes sense. If you want to filter out the text column, you can select the columns you want by using the `select` command

```
$df | dfr aggregate sum | dfr select int_1 int_2 float_-  
1 float_2
```

#	int_1	int_2	float_1	float_2
0	40	145	4.5000	46.0000

You can even store the result from this aggregation as you would store any other Nushell variable

```
> let res = ($df | dfr aggregate sum | dfr select int_-  
1 int_2 float_1 float_2)
```

And now we have two dataframes stored in memory

```
> dfr list
```

#	name	rows	columns
0	\$df	10	8
1	\$res	1	4

Pretty neat, isn't it?

You can perform several aggregations on the dataframe in order to extract basic information from the dataframe and do basic data analysis on your brand new dataframe.

## Joining a DataFrame

It is also possible to join two dataframes using a column as reference. We are going to join our mini dataframe with another mini dataframe. Copy these lines in another file and create the corresponding dataframe (for these examples we are going to call it `test_small_a.csv`)

```
int_1a,int_2,float_1,float_2,first
9,14,0.4,3.0,a
8,13,0.3,2.0,a
7,12,0.2,1.0,a
6,11,0.1,0.0,b
```

We use the `dfr open` command to create the new variable

```
> let df_a = (dfr open test_small_a.csv)
```

Now, with the second dataframe loaded in memory we can join them using the column called `int_1` from the left dataframe and the column `int_1a` from the right dataframe

```
> $df | dfr join $df_a -l [int_1] -r [int_1a]
```

#	int_1	int_2	float_1	float_2	first	second
third	word	int_2_right	float_1_right	float_2_		
right	first_right					
0	6	16	0.6000	5.0000	b	a
a	second		11		0.1000	0.
0000	b					
1	7	17	0.7000	6.0000	b	c
a	third		12		0.2000	1.
0000	a					
2	8	18	0.8000	7.0000	c	c
b	eight		13		0.3000	2.
0000	a					
3	9	19	0.9000	8.0000	c	c
b	ninth		14		0.4000	3.
0000	a					

::: tip In Nu when a command has multiple arguments that are expecting multiple values we use brackets `[]` to enclose those values. In the case of `dfr join` we can join on multiple columns as long as they have the same type, for example we could have done `$df | dfr join $df_a -l [int_1 int_2] -r [int_1a int_2]` :::

By default, the join command does an inner join, meaning that it will keep the rows where both dataframes share the same value. You can select a left join to keep the missing rows from the left dataframe. You can also save this result in order to use it for further operations.

## DataFrame group-by

One of the most powerful operations that can be performed with a DataFrame is the **group-by**. This command will allow you to perform aggregation operations based on a grouping criteria. In Nushell, a **GroupBy** is a type of object that can be stored and reused for multiple aggregations. This is quite handy, since the creation of the grouped pairs is the most expensive operation while doing group-by and there is no need to repeat it if you are planning to do multiple operations with the same group condition.

To create a **GroupBy** object you only need to use the **group-by** command

```
> let group = ($df | dfr group-by first)
> $group

#   property  value
0   group by   first
```

When printing the **GroupBy** object we can see the columns that are used as criteria to group the dataframe. Using the **GroupBy** we can aggregate the dataframe using multiple operations

```
$group | dfr aggregate sum

#   first  int_1      int_2      float_1      float_-
2
0   a          6        36        0.6000        4.
0000
1   b         17        62        2.2000       18.
```

```
0000
  2  c          17          47          1.7000          24.
0000
```

And using the same **GroupBy** you can perform now another operation on the whole dataframe, like **min** in this case

```
$group | aggregate min

#  first  int_1      int_2      float_1      float_-
2
  0  a          1        11        0.1000        1.
0000
  1  b          0        14        0.4000        3.
0000
  2  c          0        10        0.0000        7.
0000
```

The created **GroupBy** object is so handy that it can even be used as a base for pivoting a table. As an example, let's use the column called **second** as the pivot column and the column **float\_1** as the value column

```
> $group | dfr pivot second float_1 sum

#  first      b      a      c
  0  a      0.6000
  1  c              1.7000
  2  b      1.5000  0.7000
```

::: tip a pivot operation is a way to aggregate data based on two columns. In the previous example, the result of the pivot command produced a table that represents the sum of all the values in the column **float\_1** that are shared between columns **first** (now the rows)

and **second** (now the columns). So, the value of **1.5** shown in row **b** and column **a** is the sum of all the floats where the column **first** is **b** and column **second** is **a** :::

As you can see, the **GroupBy** object is a very powerful variable and it is worth keeping in memory while you explore your dataset.

## Creating Dataframes

It is also possible to construct dataframes from basic Nushell primitives, such as integers, decimals, or strings. Let's create a small dataframe using the command **to-df**.

```
> let a = ([[a b]; [1 2] [3 4] [5 6]] | dfr to-df)
> $a
```

```
#   b   a
0   2   1
1   4   3
2   6   5
```

::: tip For the time being, not all of Nushell primitives can be converted into a dataframe. This will change in the future, as the dataframe feature matures :::

We can append columns to a dataframe in order to create a new variable. As an example, let's append two columns to our mini dataframe **\$a**

```
> let a2 = ($a | dfr with-column $a.a --name a2 | dfr with-
column $a.a --name a3)
```

```
#   b   a   a2   a3
0   2   1    1    1
1   4   3    3    3
2   6   5    5    5
```

Nushell’s powerful piping syntax allows us to create new dataframes by taking data from other dataframes and appending it to them. Now, if you list your dataframes you will see in total four dataframes

```
> dfr list
```

#	name	rows	columns
0	\$a	3	2
1	\$a2	3	4
2	\$df_a	4	5
3	\$df	10	8

One thing that is important to mention is how the memory is being optimized while working with dataframes, and this is thanks to **Apache Arrow** and **Polars**. In a very simple representation, each column in a `DataFrame` is an Arrow Array, which is using several memory specifications in order to maintain the data as packed as possible (check [Arrow columnar format](https://arrow.apache.org/docs/format/Columnar.html)<sup>6</sup>). The other optimization trick is the fact that whenever possible, the columns from the dataframes are shared between dataframes, avoiding memory duplication for the same data. This means that dataframes `$a` and `$a2` are sharing the same two columns we created using the `to-df` command. For this reason, it isn’t possible to change the value of a column in a dataframe. However, you can create new columns based on data from other columns or dataframes.

## Working with Series

A **Series** is the building block of a `DataFrame`. Each Series represents a column with the same data type, and we can create multiple Series of different types, such as float, int or string.

Let’s start our exploration with Series by creating one using the `to-df` command:

---

<sup>6</sup><https://arrow.apache.org/docs/format/Columnar.html>

```
> let new = ([9 8 4] | dfr to-df)
> $new

#    0

0    9
1    8
2    4
```

We have created a new series from a list of integers (we could have done the same using floats or strings)

Series have their own basic operations defined, and they can be used to create other Series. Let's create a new Series by doing some arithmetic on the previously created column.

```
> let new_2 = ($new * 3 + 10)
> $new_2

#    0

0    37
1    34
2    22
```

**Now we have a new Series that was constructed by doing basic opera**

:: tip If you want to see how many variables you have stored in memory you can use `$scope.variables` :::

Let's rename our previous Series so it has a memorable name

```
> let new_2 = ($new_2 | dfr rename memorable)
> $new_2

#    memorable

0          37
```

1	34
2	22

We can also do basic operations with two Series as long as they have the same data type

```
> $new - $new_2
```

```
#    sub_0_0
0      -28
1      -26
2      -18
```

And we can add them to previously defined dataframes

```
> let new_df = ($a | dfr with-column $new --name new_col)
```

```
> $new_df
```

```
#    b    a  new_col
0    2    1        9
1    4    3        8
2    6    5        4
```

The Series stored in a Dataframe can also be used directly, for example, we can multiply columns **a** and **b** to create a new Series

```
> $new_df.a * $new_df.b
```

```
#    mul_a_b
0          2
```

```
1      12
2      30
```

and we can start piping things in order to create new columns and dataframes

```
> let $new_df = ($new_df | dfr with-column ($new_df.a *
$new_df.b / $new_df.new_col) --name my_sum)
> let $new_df
```

```
#   b   a  new_col  my_sum
0   2   1         9       0
1   4   3         8       1
2   6   5         4       7
```

Nushell's piping system can help you create very interesting workflows.

## Series and masks

Series have another key use in when working with DataFrames, and it is the fact that we can build boolean masks out of them. Let's start by creating a simple mask using the equality operator

```
> let mask = ($new == 8)
> $mask
```

```
#   new_col
0  false
1   true
2  false
```

and with this mask we can now filter a dataframe, like this

```
> $new_df | dfr filter-with $mask
```

```
#   a   b  new_col  my_sum
0   3   4         8       1
```

Now we have a new dataframe with only the values where the mask was true.

The masks can also be created from Nushell lists, for example:

```
> let mask1 = ([true true false] | dfr to-df mask)
> $new_df | dfr filter-with $mask1
```

```
#   a   b  new_col  my_sum
0   1   2         9       0
1   3   4         8       1
```

To create complex masks, we have the AND

```
> $mask && $mask1
```

```
#   and_new_col_mask
0   false
1   true
2   false
```

and OR operations

```
> $mask || $mask1
```

```
#   or_new_col_mask
```

```
0  true
1  true
2  false
```

We can also create a mask by checking if some values exist in other Series. Using the first dataframe that we created we can do something like this

```
> let mask3 = ($df.first | dfr is-in ([b c] | dfr to-df)
)

#  first

0  false
1  false
2  false
3  true
4  true
5  true
6  true
7  true
8  true
9  true
```

and this new mask can be used to filter the dataframe

```
> $df | dfr filter-with $mask3

#  int_1  int_2  float_1  float_2  first  second
third   word
0      4    14    0.4000    3.0000  b      a
c      second
1      0    15    0.5000    4.0000  b      a
a      third
2      6    16    0.6000    5.0000  b      a
```

a	second					
3	7	17	0.7000	6.0000	b	c
a	third					
4	8	18	0.8000	7.0000	c	c
b	eight					
5	9	19	0.9000	8.0000	c	c
b	ninth					
6	0	10	0.0000	9.0000	c	c
b	ninth					

Another operation that can be done with masks is setting or replacing a value from a series. For example, we can change the value in the column `first` where the value is equal to `a`

```
> $df.first | dfr set new --mask ($df.first =~ a)
```

```
# string
```

```
0 new
1 new
2 new
3 b
4 b
5 b
6 b
7 c
8 c
9 c
```

## Series as indices

Series can be also used as a way of filtering a dataframe by using them as a list of indices. For example, let's say that we want to get rows 1, 4, and 6 from our original dataframe. With that in mind, we can use the next command to extract that information

```
> let indices = ([1 4 6] | dfr to-df)
> $df | dfr take $indices
```

#	int_1	int_2	float_1	float_2	first	second
third	word					
0	2	12	0.2000	1.0000	a	b
c	second					
1	0	15	0.5000	4.0000	b	a
a	third					
2	7	17	0.7000	6.0000	b	c
a	third					

The command **take** is very handy, especially if we mix it with other commands. Let's say that we want to extract all rows for the first duplicated element for column **first**. In order to do that, we can use the command **dfr arg-unique** as shown in the next example

```
> let indices = ($df.first | dfr arg-unique)
> $df | dfr take $indices
```

#	int_1	int_2	float_1	float_2	first	second
third	word					
0	1	11	0.1000	1.0000	a	b
c	first					
1	4	14	0.4000	3.0000	b	a
c	second					
2	8	18	0.8000	7.0000	c	c
b	eight					

**Or what if we want to create a new sorted dataframe using a column**  
 :: tip The same result could be accomplished using the command  
**sort** ::

```
> let indices = ($df.word | dfr arg-sort)
> $df | dfr take $indices
```

#	int_1	int_2	float_1	float_2	first	second
third	word					
0	8	18	0.8000	7.0000	c	c
b	eight					
1	1	11	0.1000	1.0000	a	b
c	first					
2	9	19	0.9000	8.0000	c	c
b	ninth					
3	0	10	0.0000	9.0000	c	c
b	ninth					
4	2	12	0.2000	1.0000	a	b
c	second					
5	4	14	0.4000	3.0000	b	a
c	second					
6	6	16	0.6000	5.0000	b	a
a	second					
7	3	13	0.3000	2.0000	a	b
c	third					
8	0	15	0.5000	4.0000	b	a
a	third					
9	7	17	0.7000	6.0000	b	c
a	third					

And finally, we can create new Series by setting a new value in the marked indices. Have a look at the next command

```
> let indices = ([0 2] | dfr to-df);
> $df.int_1 | dfr set-with-idx 123 --indices $indices
```

#	int_1
0	123
1	2

```
2      123
3        4
4        0
5        6
6        7
7        8
8        9
9        0
```

## Unique values

Another operation that can be done with **Series** is to search for unique values in a list or column. Lets use again the first dataframe we created to test these operations.

The first and most common operation that we have is **value\_counts**. This command calculates a count of the unique values that exist in a Series. For example, we can use it to count how many occurrences we have in the column **first**

```
> $df.first | dfr value-counts
```

```
#   first  counts
0    b         4
1    c         3
2    a         3
```

As expected, the command returns a new dataframe that can be used to do more queries.

Continuing with our exploration of **Series**, the next thing that we can do is to only get the unique values from a series, like this

```
> $df.first | dfr unique
```

```
#   first
```

```

0  c
1  b
2  a

```

Or we can get a mask that we can use to filter out the rows where data is unique or duplicated. For example, we can select the rows for unique values in column `word`

```
> $df | dfr filter-with ($df.word | dfr is-unique)
```

```

#  int_1  int_2  float_1  float_2  first  second
third word

0    1    11    0.1000   1.0000   a      b
c    first
1    8    18    0.8000   7.0000   c      c
b    eight

```

Or all the duplicated ones

```
> $df | dfr filter-with ($df.word | dfr is-duplicated)
```

```

#  int_1  int_2  float_1  float_2  first  second
third word

0    2    12    0.2000   1.0000   a      b
c    second
1    3    13    0.3000   2.0000   a      b
c    third
2    4    14    0.4000   3.0000   b      a
c    second
3    0    15    0.5000   4.0000   b      a
a    third
4    6    16    0.6000   5.0000   b      a
a    second
5    7    17    0.7000   6.0000   b      c
a    third

```

6	9	19	0.9000	8.0000	c	c
b	ninth					
7	0	10	0.0000	9.0000	c	c
b	ninth					

## Dataframe commands

So far we have seen quite a few operations that can be done using `DataFrames` commands. However, the commands we have used so far are not all the commands available to work with data and be assured that there will be more as the feature becomes more stable.

The next list shows the available dataframe commands with their descriptions, and whenever possible, their analogous Nushell command.

Command Name	Applies To	Description	Nushell Equivalent
aggregate	DataFrame, GroupBy, Series	Performs an aggregation operation on a dataframe, groupby or series object	math
all-false	Series	Returns true if all values are false	all?
all-true	Series	Returns true if all values are true	
arg-max	Series	Return index for max value in series	
arg-min	Series	Return index for min value in series	
arg-sort	Series	Returns indexes for a sorted series	
arg-true	Series	Returns indexes where values are true	
arg-unique	Series	Returns indexes for unique values	
column	DataFrame	Returns the selected column as Series	get
count-null	Series	Counts null values	drop
count-unique	Series	Counts unique value	
drop	DataFrame	Creates a new dataframe by dropping the selected columns	
drop-duplicates	DataFrame	Drops duplicate values in dataframe	
drop-nulls	DataFrame,	Drops null	

## Future of Dataframes

We hope that by the end of this page you have a solid grasp of how to use the dataframe commands. As you can see they offer powerful operations that can help you process data faster and natively.

However, the future of these dataframes is still very experimental. New commands and tools that take advantage of these commands will be added as they mature. For example, the next step for dataframes is the introduction of Lazy Dataframes. These will allow you to define complex data operations that will be executed until you decide to “finish” the pipe. This will give Nushell the chance to select the optimal plan to query the data you would be asking for.

Keep visiting this book in order to check the new things happening to dataframes and how they can help you process data faster and efficiently.

# Chapter 33

## Metadata

In using Nu, you may have come across times where you felt like there was something extra going on behind the scenes. For example, let's say that you try to open a file that Nu supports only to forget and try to convert again:

```
> open Cargo.toml | from toml
error: Expected a string from pipeline
- shell:1:18
1 | open Cargo.toml | from toml
  |                      ~~~~~~ requires string input
- shell:1:5
1 | open Cargo.toml | from toml
  |      ~~~~~~ object originates from here
```

The error message tells us not only that what we gave `from toml` wasn't a string, but also where the value originally came from. How would it know that?

Values that flow through a pipeline in Nu often have a set of additional information, or metadata, attached to them. These are known as tags, like the tags on an item in a store. These tags don't affect the data, but they give Nu a way to improve the experience of working with that data.

Let's run the `open` command again, but this time, we'll look at the tags it gives back:

```
> open Cargo.toml | metadata  
  
span      {record 2 fields}
```

Currently, we track only the span of where values come from. Let's take a closer look at that:

```
> open Cargo.toml | metadata | get span  
  
start    5  
end      15
```

The span “start” and “end” here refer to where the underline will be in the line. If you count over 5, and then count up to 15, you'll see it lines up with the “Cargo.toml” filename. This is how the error we saw earlier knew what to underline.

## Chapter 34

# Creating your own errors

Using the **metadata** information, you can create your own custom error messages. Error messages are built of multiple parts:

- The title of the error
- The label of error message, which includes both the text of the label and the span to underline

You can use the **error make** command to create your own error messages. For example, let's say you had your own command called **my-command** and you wanted to give an error back to the caller about something wrong with a parameter that was passed in.

First, you can take the span of where the argument is coming from:

```
let span = (metadata $x).span;
```

Next, you can create an error using the **error make** command. This command takes in a record that describes the error to create:

```
error make {msg: "this is fishy", label: {text: "fish right  
here", start: $span.start, end: $span.end } }
```

Together with your custom command, it might look like this:

```
def my-command [x] {  
  let span = (metadata $x).span;  
  error make {
```

```
        msg: "this is fishy",
        label: {
            text: "fish right here",
            start: $span.start,
            end: $span.end
        }
    }
}
```

When called with a value, we'll now see an error message returned:

```
> my-command 100

Error:
  × this is fishy
    [entry #5:1:1]
1  my-command 100
   .
   .
   fish right here
```

# Chapter 35

## Parallelism

Nushell now has early support for running code in parallel. This allows you to process elements of a stream using more hardware resources of your computer.

You will notice these commands with their characteristic **par-** naming. Each corresponds to a non-parallel version, allowing you to easily write code in a serial style first, and then go back and easily convert serial scripts into parallel scripts with a few extra characters.

### par-each

The most common parallel command is **par-each**, a companion to the **each** command.

Like **each**, **par-each** works on each element in the pipeline as it comes in, running a block on each. Unlike **each**, **par-each** will do these operations in parallel.

Let's say you wanted to count the number of files in each sub-directory of the current directory. Using **each**, you could write this as:

```
> ls | where type == dir | each { |it|  
    { name: $it.name, len: (ls $it.name | length) }  
}
```

We create a record for each entry, and fill it with the name of the directory and the count of entries in that sub-directory.

On your machine, the times may vary. For this machine, it took 21 milliseconds for the current directory.

Now, since this operation can be run in parallel, let's convert the above to parallel by changing **each** to **par-each**:

```
> ls | where type == dir | par-each { |it|  
  { name: $it.name, len: (ls $it.name | length) }  
}
```

On this machine, it now runs in 6ms. That's quite a difference!

As a side note: Because **environment variables are scoped**, you can use **par-each** to work in multiple directories in parallel (notice the **cd** command):

```
> ls | where type == dir | par-each { |it|  
  { name: $it.name, len: (cd $it.name; ls | length) }  
}
```

You'll notice, if you look at the results, that they come back in different orders each run (depending on the number of hardware threads on your system). As tasks finish, and we get the correct result, we may need to add additional steps if we want our results in a particular order. For example, for the above, we may want to sort the results by the "name" field. This allows both **each** and **par-each** versions of our script to give the same result.

# Chapter 36

## Plugins

Nu can be extended using plugins. Plugins behave much like Nu's built-in commands, with the added benefit that they can be added separately from Nu itself.

Nu plugins are executables; Nu launches them as needed and communicates with them over `stdin`, `stdout`, and `stderr`<sup>1</sup>. Nu plugins can use either JSON or `Cap'n Proto`<sup>2</sup> as their communication encoding.

### Adding a plugin

To add a plugin, call the `register` command to tell Nu where to find it. As you do, you'll need to also tell Nushell what encoding the plugin uses.

Linux+macOS:

```
> register --encoding=capnp ./my_plugins/my-cool-plugin
```

Windows:

```
> register --encoding=capnp .\my_plugins\my-cool-plugin.exe
```

When `register` is called:

---

<sup>1</sup>[https://en.wikipedia.org/wiki/Standard\\_streams](https://en.wikipedia.org/wiki/Standard_streams)

<sup>2</sup><https://capnproto.org/>

1. Nu launches the plugin and sends it a “Signature” message over stdin
2. The plugin responds via stdout with a message containing its signature (name, description, arguments, flags, and more)
3. Nu saves the plugin signature in the file at `$nu.plugin-path`, so registration is persisted across multiple launches

Once registered, the plugin is available as part of your set of commands:

```
> help commands | where is_plugin == true
```

## Examples

Nu’s main repo contains example plugins that are useful for learning how the plugin protocol works:

- [Rust](#)<sup>3</sup>
- [Python](#)<sup>4</sup>

## Debugging

The simplest way to debug a plugin is to print to stderr; plugins’ standard error streams are redirected through Nu and displayed to the user.

## Help

Nu’s plugin documentation is a work in progress. If you’re unsure about something, the #plugins channel on [the Nu Discord](#)<sup>5</sup> is a great place to ask questions!

## Chapter 37

# Regular expressions

Regular expressions in Nushell’s commands are handled by the `rust-lang/regex` crate. If you want to know more, check the crate documentation: “[regex]<https://github.com/rust-lang/regex>”.

# Chapter 38

## Command Reference

To see all commands in Nushell, run `help commands`

### alias

**version:** 0.61.0

#### usage:

Alias a command (with optional flags) to a new name

### Signature

```
> alias (name) (initial_value)
```

### Parameters

- **name:** name of the alias
- **initial\_value:** equals sign followed by value

### Examples

Alias `ll` to `ls -l`

```
> alias ll = ls -l
```

## all?

**version:** 0.61.0

### usage:

Test if every element of the input matches a predicate.

## Signature

```
> all? (predicate)
```

## Parameters

- **predicate:** the predicate that must match

## Examples

Find if services are running

```
> echo [[status]; [UP] [UP]] | all? status == UP
```

Check that all values are even

```
> echo [2 4 6 8] | all? ($it mod 2) == 0
```

## ansi

**version:** 0.61.0

### usage:

Output ANSI codes to change color.

## Signature

```
> ansi (code) --escape --osc --list
```

## Parameters

- **code**: the name of the code to use like 'green' or 'reset' to reset the color
- **--escape**: escape sequence without the escape character(s)
- **--osc**: operating system command (ocs) escape sequence without the escape character(s)
- **--list**: list available ansi code names

## Examples

Change color to green

```
> ansi green
```

Reset the color

```
> ansi reset
```

Use ansi to color text (rb = red bold, gb = green bold, pb = purple bold)

```
> echo [(ansi rb) Hello " " (ansi gb) Nu " " (ansi pb)
World (ansi reset)] | str collect
```

Use ansi to color text (italic bright yellow on red 'Hello' with green bold 'Nu' and purple bold 'World')

```
> echo [(ansi -e '3;93;41m') Hello (ansi reset) " " (ansi
gb) Nu " " (ansi pb) World (ansi reset)] | str collect
```

Use ansi to color text with a style (blue on red in bold)

```
> $("ansi -e { fg: '#0000ff' bg: '#ff0000' attr: b })Hello
Nu World(ansi reset)"
```

## ansi gradient

**version:** 0.61.0

## usage:

Draw text with a provided start and end code making a gradient

## Signature

```
> ansi gradient ...column path --fgstart --fgend --bgstart -  
-bgend
```

## Parameters

- ...column path: optionally, draw gradients using text from column paths
- --fgstart {string}: foreground gradient start color in hex (0x123456)
- --fgend {string}: foreground gradient end color in hex
- --bgstart {string}: background gradient start color in hex
- --bgend {string}: background gradient end color in hex

## Examples

draw text in a gradient with foreground start and end colors

```
> echo 'Hello, Nushell! This is a gradient.' | ansi gradient  
--fgstart 0x40c9ff --fgend 0xe81cff
```

draw text in a gradient with foreground start and end colors and background start and end colors

```
> echo 'Hello, Nushell! This is a gradient.' | ansi gradient  
--fgstart 0x40c9ff --fgend 0xe81cff --bgstart 0xe81cff  
--bgend 0x40c9ff
```

draw text in a gradient by specifying foreground start color - end color is assumed to be black

```
> echo 'Hello, Nushell! This is a gradient.' | ansi gradient  
--fgstart 0x40c9ff
```

draw text in a gradient by specifying foreground end color - start color is assumed to be black

```
> echo 'Hello, Nushell! This is a gradient.' | ansi gradient
--fgend 0xe81cff
```

## ansi strip

**version:** 0.61.0

### usage:

Strip ANSI escape sequences from a string

### Signature

```
> ansi strip ...column path
```

### Parameters

- `...column path`: optionally, remove ANSI sequences by column paths

### Examples

Strip ANSI escape sequences from a string

```
> echo [ (ansi green) (ansi cursor_on) "hello" ] | str
collect | ansi strip
```

## any?

**version:** 0.61.0

### usage:

Tests if any element of the input matches a predicate.

### Signature

```
> any? (predicate)
```

## Parameters

- **predicate:** the predicate that must match

## Examples

Find if a service is not running

```
> echo [[status]; [UP] [DOWN] [UP]] | any? status == DOWN
```

Check if any of the values is odd

```
> echo [2 4 1 6 8] | any? ($it mod 2) == 1
```

## append

**version:** 0.61.0

### usage:

Append any number of rows to a table.

## Signature

```
> append (row)
```

## Parameters

- **row:** the row, list, or table to append

## Examples

Append one Int item

```
> [0,1,2,3] | append 4
```

Append three Int items

```
> [0,1] | append [2,3,4]
```

Append Ints and Strings

```
> [0,1] | append [2,nu,4,shell]
```

## benchmark

**version:** 0.61.0

### usage:

Time the running time of a block

### Signature

```
> benchmark (block)
```

### Parameters

- **block:** the block to run

## Examples

Benchmarks a command within a block

```
> benchmark { sleep 500ms }
```

## build-string

**version:** 0.61.0

### usage:

Create a string from the arguments.

### Signature

```
> build-string ...rest
```

### Parameters

- **...rest:** list of string

## Examples

Builds a string from letters a b c

```
> build-string a b c
```

Builds a string from letters a b c

```
> build-string (1 + 2) = one ' ' plus ' ' two
```

## cal

**version:** 0.61.0

### usage:

Display a calendar.

## Signature

```
> cal --year --quarter --month --full-year --week-start --month-  
names
```

## Parameters

- **--year:** Display the year column
- **--quarter:** Display the quarter column
- **--month:** Display the month column
- **--full-year {int}:** Display a year-long calendar for the specified year
- **--week-start {string}:** Display the calendar with the specified day as the first day of the week
- **--month-names:** Display the month names instead of integers

## Examples

This month's calendar

```
> cal
```

The calendar for all of 2012

```
> cal --full-year 2012
```

This month's calendar with the week starting on monday

```
> cal --week-start monday
```

## cd

**version:** 0.61.0

### usage:

Change directory.

## Signature

```
> cd (path)
```

## Parameters

- **path:** the path to change to

## Examples

Change to your home directory

```
> cd ~
```

## char

**version:** 0.61.0

### usage:

Output special characters (e.g., 'newline').

## Signature

```
> char (character) ...rest --list --unicode
```

## Parameters

- **character**: the name of the character to output
- **...rest**: multiple Unicode bytes
- **--list**: List all supported character names
- **--unicode**: Unicode string i.e. 1f378

## Examples

Output newline

```
> char newline
```

Output prompt character, newline and a hamburger character

```
> echo [(char prompt) (char newline) (char hamburger)]  
| str collect
```

Output Unicode character

```
> char -u 1f378
```

Output multi-byte Unicode character

```
> char -u 1F468 200D 1F466 200D 1F466
```

## clear

**version:** 0.61.0

### usage:

Clear the terminal.

## Signature

```
> clear
```

## Examples

Clear the terminal

```
> clear
```

## collect

**version:** 0.61.0

### usage:

Collect the stream and pass it to a block.

## Signature

```
> collect (block)
```

## Parameters

- **block:** the block to run once the stream is collected

## Examples

Use the second value in the stream

```
> echo 1 2 3 | collect { |x| echo $x.1 }
```

## columns

**version:** 0.61.0

### usage:

Show the columns in the input.

## Signature

```
> columns
```

## Examples

Get the columns from the table

```
> [[name,age,grade]; [bill,20,a]] | columns
```

Get the first column from the table

```
> [[name,age,grade]; [bill,20,a]] | columns | first
```

Get the second column from the table

```
> [[name,age,grade]; [bill,20,a]] | columns | select 1
```

## compact

**version:** 0.61.0

### usage:

Creates a table with non-empty rows.

## Signature

```
> compact ...columns
```

## Parameters

- `...columns`: the columns to compact from the table

## Examples

Filter out all records where ‘Hello’ is null (returns nothing)

```
> echo [["Hello" "World"]; [$nothing 3]] | compact Hello
```

Filter out all records where ‘World’ is null (Returns the table)

```
> echo ["Hello" "World"]; [$nothing 3] | compact World
```

Filter out all instances of nothing from a list (Returns [1,2])

```
> echo [1, $nothing, 2] | compact
```

## complete

**version:** 0.61.0

### usage:

Complete the external piped in, collecting outputs and exit code

## Signature

```
> complete
```

## Examples

Run the external completion

```
> ^external arg1 | complete
```

## cp

**version:** 0.61.0

### usage:

Copy files.

## Signature

```
> cp (source) (destination) --recursive
```

## Parameters

- **source:** the place to copy from
- **destination:** the place to copy to
- **--recursive:** copy recursively through subdirectories

## Examples

Copy myfile to dir\_b

```
> cp myfile dir_b
```

Recursively copy dir\_a to dir\_b

```
> cp -r dir_a dir_b
```

## dataframe

**version:** 0.61.0

**usage:**

Deprecated command

## Signature

```
> dataframe
```

## date

**version:** 0.61.0

**usage:**

Date-related commands

## Signature

```
> date
```

## date format

**version:** 0.61.0

### usage:

Format a given date using a format string.

### Signature

```
> date format (format string) --list
```

### Parameters

- **format string:** the desired date format
- **--list:** lists strftime cheatsheet

### Examples

Format a given date using the default format (RFC 2822).

```
> "2021-10-22 20:00:12 +01:00" | date format
```

Format a given date using a given format string.

```
> date format '%Y-%m-%d'
```

Format a given date using a given format string.

```
> date format "%Y-%m-%d %H:%M:%S"
```

Format a given date using a given format string.

```
> "2021-10-22 20:00:12 +01:00" | date format "%Y-%m-%d"
```

## date humanize

**version:** 0.61.0

**usage:**

Print a 'humanized' format for the date, relative to now.

**Signature**

```
> date humanize
```

**Examples**

Print a 'humanized' format for the date, relative to now.

```
> date humanize
```

Print a 'humanized' format for the date, relative to now.

```
> "2021-10-22 20:00:12 +01:00" | date humanize
```

**date list-timezone**

version: 0.61.0

**usage:**

List supported time zones.

**Signature**

```
> date list-timezone
```

**Examples**

Show timezone(s) that contains 'Shanghai'

```
> date list-timezone | where timezone =~ Shanghai
```

**date now**

version: 0.61.0

**usage:**

Get the current date.

**Signature**

```
> date now
```

**Examples**

Get the current date and display it in a given format string.

```
> date now | date format "%Y-%m-%d %H:%M:%S"
```

Get the time duration from 2019-04-30 to now

```
> (date now) - 2019-05-01
```

Get the time duration since a more accurate time

```
> (date now) - 2019-05-01T04:12:05.20+08:00
```

Get current time in full RFC3339 format with timezone

```
> date now | debug
```

**date to-record**

**version:** 0.61.0

**usage:**

Convert the date into a structured table.

**Signature**

```
> date to-record
```

## Examples

Convert the current date into a structured table.

```
> date to-table
```

Convert the current date into a structured table.

```
> date now | date to-record
```

Convert a given date into a structured table.

```
> '2020-04-12 22:10:57 +0200' | date to-record
```

## date to-table

version: 0.61.0

### usage:

Convert the date into a structured table.

## Signature

```
> date to-table
```

## Examples

Convert the date into a structured table.

```
> date to-table
```

Convert the date into a structured table.

```
> date now | date to-table
```

Convert a given date into a structured table.

```
> '2020-04-12 22:10:57 +0200' | date to-table
```

## date to-timezone

**version:** 0.61.0

### usage:

Convert a date to a given time zone.

### Signature

```
> date to-timezone (time zone)
```

### Parameters

- **time zone:** time zone description

### Examples

Get the current date in UTC+05:00

```
> date now | date to-timezone +0500
```

Get the current local date

```
> date now | date to-timezone local
```

Get the current date in Hawaii

```
> date now | date to-timezone US/Hawaii
```

Get the current date in Hawaii

```
> "2020-10-10 10:00:00 +02:00" | date to-timezone "+0500"
```

## debug

**version:** 0.61.0

**usage:**

Debug print the value(s) piped in.

**Signature**

```
> debug --raw
```

**Parameters**

- `--raw`: Prints the raw value representation

**Examples**

Print the value of a string

```
> 'hello' | debug
```

Print the value of a table

```
> echo [[version patch]; [0.1.0 false] [0.1.1 true] [0.2.0 false]] | debug
```

**decode**

**version:** 0.61.0

**usage:**

Decode bytes as a string.

**Signature**

```
> decode (encoding)
```

**Parameters**

- `encoding`: the text encoding to use

## Examples

Decode the output of an external command

```
> cat myfile.q | decode utf-8
```

## def-env

**version:** 0.61.0

### usage:

Define a custom command, which participates in the caller environment

## Signature

```
> def-env (def_name) (params) (block)
```

## Parameters

- **def\_name:** definition name
- **params:** parameters
- **block:** body of the definition

## Examples

Set environment variable by call a custom command

```
> def-env foo [] { let-env BAR = "BAZ" }; foo; $env.BAR
```

## def

**version:** 0.61.0

### usage:

Define a custom command

## Signature

```
> def (def_name) (params) (block)
```

## Parameters

- `def_name`: definition name
- `params`: parameters
- `block`: body of the definition

## Examples

Define a command and run it

```
> def say-hi [] { echo 'hi' }; say-hi
```

Define a command and run it with parameter(s)

```
> def say-sth [sth: string] { echo $sth }; say-sth hi
```

## default

**version:** 0.61.0

### usage:

Sets a default row's column if missing.

## Signature

```
> default (default value) (column name)
```

## Parameters

- `default value`: the value to use as a default
- `column name`: the name of the column

## Examples

Give a default 'target' column to all file entries

```
> ls -la | default 'nothing' target
```

Default the \$nothing value in a list

```
> [1, 2, $nothing, 4] | default 3
```

## describe

**version:** 0.61.0

### usage:

Describe the value(s) piped in.

## Signature

```
> describe
```

## Examples

Describe the type of a string

```
> 'hello' | describe
```

## detect columns

**version:** 0.61.0

### usage:

Attempt to automatically split text into multiple columns

## Signature

```
> detect columns --skip --no-headers
```

## Parameters

- `--skip {int}`: number of rows to skip before detecting
- `--no-headers`: don't detect headers

## Examples

Splits string across multiple columns

```
> echo 'a b c' | detect columns -n
```

Splits a multi-line string into columns with headers detected

```
> echo $'c1 c2 c3(char nl)a b c' | detect columns
```

## dfr

**version:** 0.61.0

### usage:

Dataframe commands

## Signature

```
> dfr
```

## dfr aggregate

**version:** 0.61.0

### usage:

Performs an aggregation operation on a dataframe and groupby object

## Signature

```
> dfr aggregate (operation_name) --quantile --explicit
```

## Parameters

- **operation\_name**: Dataframes: mean, sum, min, max, quantile, median, var, std GroupBy: mean, sum, min, max, first, last, nunique, quantile, median, var, std, count
- **--quantile {number}**: quantile value for quantile operation
- **--explicit**: returns explicit names for groupby aggregations

## Examples

Aggregate sum by grouping by column a and summing on col b

```
> [[a b]; [one 1] [one 2]] | dfr to-df | dfr group-by a  
| dfr aggregate sum
```

Aggregate sum in dataframe columns

```
> [[a b]; [4 1] [5 2]] | dfr to-df | dfr aggregate sum
```

Aggregate sum in series

```
> [4 1 5 6] | dfr to-df | dfr aggregate sum
```

## dfr all-false

**version:** 0.61.0

### usage:

Returns true if all values are false

## Signature

```
> dfr all-false
```

## Examples

Returns true if all values are false

```
> [false false false] | dfr to-df | dfr all-false
```

Checks the result from a comparison

```
> let s = ([5 6 2 10] | dfr to-df);  
  let res = ($s > 9);  
  $res | dfr all-false
```

## dfr all-true

version: 0.61.0

### usage:

Returns true if all values are true

### Signature

```
> dfr all-true
```

### Examples

Returns true if all values are true

```
> [true true true] | dfr to-df | dfr all-true
```

Checks the result from a comparison

```
> let s = ([5 6 2 8] | dfr to-df);  
  let res = ($s > 9);  
  $res | dfr all-true
```

## dfr append

version: 0.61.0

### usage:

Appends a new dataframe

## Signature

```
> dfr append (other) --col
```

## Parameters

- **other**: dataframe to be appended
- **--col**: appends in col orientation

## Examples

Appends a dataframe as new columns

```
> let a = ([[a b]; [1 2] [3 4]] | dfr to-df);  
$a | dfr append $a
```

Appends a dataframe merging at the end of columns

```
> let a = ([[a b]; [1 2] [3 4]] | dfr to-df);  
$a | dfr append $a --col
```

## dfr arg-max

**version:** 0.61.0

### usage:

Return index for max value in series

## Signature

```
> dfr arg-max
```

## Examples

Returns index for max value

```
> [1 3 2] | dfr to-df | dfr arg-max
```

## dfr arg-min

**version:** 0.61.0

### usage:

Return index for min value in series

### Signature

```
> dfr arg-min
```

### Examples

Returns index for min value

```
> [1 3 2] | dfr to-df | dfr arg-min
```

## dfr arg-sort

**version:** 0.61.0

### usage:

Returns indexes for a sorted series

### Signature

```
> dfr arg-sort --reverse --nulls-last
```

### Parameters

- **--reverse:** reverse order
- **--nulls-last:** nulls ordered last

### Examples

Returns indexes for a sorted series

```
> [1 2 2 3 3] | dfr to-df | dfr arg-sort
```

Returns indexes for a sorted series

```
> [1 2 2 3 3] | dfr to-df | dfr arg-sort -r
```

## dfr arg-true

**version:** 0.61.0

### usage:

Returns indexes where values are true

## Signature

```
> dfr arg-true
```

## Examples

Returns indexes where values are true

```
> [false true false] | dfr to-df | dfr arg-true
```

## dfr arg-unique

**version:** 0.61.0

### usage:

Returns indexes for unique values

## Signature

```
> dfr arg-unique
```

## Examples

Returns indexes for unique values

```
> [1 2 2 3 3] | dfr to-df | dfr arg-unique
```

## dfr as-date

version: 0.61.0

### usage:

Converts string to date.

## Signature

```
> dfr as-date (format) --not-exact
```

## Parameters

- **format**: formatting date string
- **--not-exact**: the format string may be contained in the date (e.g. foo-2021-01-01-bar could match 2021-01-01)

## Examples

Converts string to date

```
> ["2021-12-30" "2021-12-31"] | dfr to-df | dfr as-datetime  
"%Y-%m-%d"
```

## dfr as-datetime

version: 0.61.0

### usage:

Converts string to datetime.

## Signature

```
> dfr as-datetime (format) --not-exact
```

## Parameters

- **format**: formatting date time string
- **--not-exact**: the format string may be contained in the date (e.g. foo-2021-01-01-bar could match 2021-01-01)

## Examples

Converts string to datetime

```
> ["2021-12-30 00:00:00" "2021-12-31 00:00:00"] | dfr to-df | dfr as-datetime "%Y-%m-%d %H:%M:%S"
```

## dfr column

**version:** 0.61.0

### usage:

Returns the selected column

## Signature

```
> dfr column (column)
```

## Parameters

- **column**: column name

## Examples

Returns the selected column as series

```
> [[a b]; [1 2] [3 4]] | dfr to-df | dfr column a
```

## dfr concatenate

version: 0.61.0

### usage:

Concatenates strings with other array

### Signature

```
> dfr concatenate (other)
```

### Parameters

- **other**: Other array with string to be concatenated

### Examples

Concatenate string

```
> let other = ([za xs cd] | dfr to-df);  
[abc abc abc] | dfr to-df | dfr concatenate $other
```

## dfr contains

version: 0.61.0

### usage:

Checks if a pattern is contained in a string

### Signature

```
> dfr contains (pattern)
```

### Parameters

- **pattern**: Regex pattern to be searched

## Examples

Returns boolean indicating if pattern was found

```
> [abc acb acb] | dfr to-df | dfr contains ab
```

## dfr count-null

**version:** 0.61.0

### usage:

Counts null values

## Signature

```
> dfr count-null
```

## Examples

Counts null values

```
> let s = ([1 1 0 0 3 3 4] | dfr to-df);  
($s / $s) | dfr count-null
```

## dfr count-unique

**version:** 0.61.0

### usage:

Counts unique values

## Signature

```
> dfr count-unique
```

## Examples

Counts unique values

```
> [1 1 2 2 3 3 4] | dfr to-df | dfr count-unique
```

## dfr cumulative

version: 0.61.0

### usage:

Cumulative calculation for a series

## Signature

```
> dfr cumulative (type) --reverse
```

## Parameters

- **type**: rolling operation
- **--reverse**: Reverse cumulative calculation

## Examples

Cumulative sum for a series

```
> [1 2 3 4 5] | dfr to-df | dfr cumulative sum
```

## dfr describe

version: 0.61.0

### usage:

Describes dataframes numeric columns

## Signature

```
> dfr describe --quantiles
```

## Parameters

- `--quantiles {table}`: optional quantiles for describe

## Examples

dataframe description

```
> [[a b]; [1 1] [1 1]] | dfr to-df | dfr describe
```

## dfr drop-duplicates

version: 0.61.0

### usage:

Drops duplicate values in dataframe

## Signature

```
> dfr drop-duplicates (subset) --maintain --last
```

## Parameters

- `subset`: subset of columns to drop duplicates
- `--maintain`: maintain order
- `--last`: keeps last duplicate value (by default keeps first)

## Examples

drop duplicates

```
> [[a b]; [1 2] [3 4] [1 2]] | dfr to-df | dfr drop-duplicates
```

## dfr drop-nulls

version: 0.61.0

**usage:**

Drops null values in dataframe

**Signature**

```
> dfr drop-nulls (subset)
```

**Parameters**

- **subset**: subset of columns to drop nulls

**Examples**

drop null values in dataframe

```
> let df = ([a b]; [1 2] [3 0] [1 2]) | dfr to-df);  
let res = ($df.b / $df.b);  
let a = ($df | dfr with-column $res --name res);  
$a | dfr drop-nulls
```

drop null values in dataframe

```
> let s = ([1 2 0 0 3 4] | dfr to-df);  
($s / $s) | dfr drop-nulls
```

**dfr drop**

**version:** 0.61.0

**usage:**

Creates a new dataframe by dropping the selected columns

**Signature**

```
> dfr drop ...rest
```

**Parameters**

- **...rest**: column names to be dropped

## Examples

drop column a

```
> [[a b]; [1 2] [3 4]] | dfr to-df | dfr drop a
```

## dfr dtypes

**version:** 0.61.0

### usage:

Show dataframe data types

## Signature

```
> dfr dtypes
```

## Examples

Dataframe dtypes

```
> [[a b]; [1 2] [3 4]] | dfr to-df | dfr dtypes
```

## dfr filter-with

**version:** 0.61.0

### usage:

Filters dataframe using a mask as reference

## Signature

```
> dfr filter-with (mask)
```

## Parameters

- **mask:** boolean mask used to filter data

## Examples

Filter dataframe using a bool mask

```
> let mask = ([true false] | dfr to-df);  
  [[a b]; [1 2] [3 4]] | dfr to-df | dfr filter-with $mask
```

## dfr first

**version:** 0.61.0

**usage:**

Creates new dataframe with first rows

## Signature

```
> dfr first (rows)
```

## Parameters

- **rows:** Number of rows for head

## Examples

Create new dataframe with head rows

```
> [[a b]; [1 2] [3 4]] | dfr to-df | dfr first 1
```

## dfr get-day

**version:** 0.61.0

**usage:**

Gets day from date

## Signature

```
> dfr get-day
```

## Examples

Returns day from a date

```
> let dt = ('2020-08-04T16:39:18+00:00' | into datetime
-z 'UTC');
let df = ([dt $dt] | dfr to-df);
$df | dfr get-day
```

## dfr get-hour

**version:** 0.61.0

### usage:

Gets hour from date

## Signature

```
> dfr get-hour
```

## Examples

Returns hour from a date

```
> let dt = ('2020-08-04T16:39:18+00:00' | into datetime
-z 'UTC');
let df = ([dt $dt] | dfr to-df);
$df | dfr get-hour
```

## dfr get-minute

**version:** 0.61.0

### usage:

Gets minute from date

## Signature

```
> dfr get-minute
```

## Examples

Returns minute from a date

```
> let dt = ('2020-08-04T16:39:18+00:00' | into datetime
-z 'UTC');
let df = ([dt $dt] | dfr to-df);
$df | dfr get-minute
```

## dfr get-month

version: 0.61.0

### usage:

Gets month from date

## Signature

```
> dfr get-month
```

## Examples

Returns month from a date

```
> let dt = ('2020-08-04T16:39:18+00:00' | into datetime
-z 'UTC');
let df = ([dt $dt] | dfr to-df);
$df | dfr get-month
```

## dfr get-nanosecond

version: 0.61.0

### usage:

Gets nanosecond from date

## Signature

```
> dfr get-nanosecond
```

## Examples

Returns nanosecond from a date

```
> let dt = ('2020-08-04T16:39:18+00:00' | into datetime
-z 'UTC');
let df = ([dt dt] | dfr to-df);
$df | dfr get-nanosecond
```

## dfr get-ordinal

version: 0.61.0

### usage:

Gets ordinal from date

## Signature

```
> dfr get-ordinal
```

## Examples

Returns ordinal from a date

```
> let dt = ('2020-08-04T16:39:18+00:00' | into datetime
-z 'UTC');
let df = ([dt dt] | dfr to-df);
$df | dfr get-ordinal
```

## dfr get-second

version: 0.61.0

### usage:

Gets second from date

## Signature

```
> dfr get-second
```

## Examples

Returns second from a date

```
> let dt = ('2020-08-04T16:39:18+00:00' | into datetime
-z 'UTC');
let df = ([dt $dt] | dfr to-df);
$df | dfr get-second
```

## dfr get-week

version: 0.61.0

### usage:

Gets week from date

## Signature

```
> dfr get-week
```

## Examples

Returns week from a date

```
> let dt = ('2020-08-04T16:39:18+00:00' | into datetime
-z 'UTC');
let df = ([dt $dt] | dfr to-df);
$df | dfr get-week
```

## dfr get-weekday

version: 0.61.0

### usage:

Gets weekday from date

## Signature

```
> dfr get-weekday
```

## Examples

Returns weekday from a date

```
> let dt = ('2020-08-04T16:39:18+00:00' | into datetime
-z 'UTC');
let df = ([dt dt] | dfr to-df);
$df | dfr get-weekday
```

## dfr get-year

version: 0.61.0

### usage:

Gets year from date

## Signature

```
> dfr get-year
```

## Examples

Returns year from a date

```
> let dt = ('2020-08-04T16:39:18+00:00' | into datetime
-z 'UTC');
let df = ([dt dt] | dfr to-df);
$df | dfr get-year
```

## dfr get

version: 0.61.0

**usage:**

Creates dataframe with the selected columns

**Signature**

```
> dfr get ...rest
```

**Parameters**

- `...rest`: column names to sort dataframe

**Examples**

Creates dataframe with selected columns

```
> [[a b]; [1 2] [3 4]] | dfr to-df | dfr get a
```

**dfr group-by**

version: 0.61.0

**usage:**

Creates a groupby object that can be used for other aggregations

**Signature**

```
> dfr group-by ...rest
```

**Parameters**

- `...rest`: groupby columns

**Examples**

Grouping by column a

```
> [[a b]; [one 1] [one 2]] | dfr to-df | dfr group-by a
```

## dfr is-duplicated

**version:** 0.61.0

### usage:

Creates mask indicating duplicated values

### Signature

```
> dfr is-duplicated
```

### Examples

Create mask indicating duplicated values

```
> [5 6 6 6 8 8 8] | dfr to-df | dfr is-duplicated
```

## dfr is-in

**version:** 0.61.0

### usage:

Checks if elements from a series are contained in right series

### Signature

```
> dfr is-in (other)
```

### Parameters

- **other:** right series

### Examples

Checks if elements from a series are contained in right series

```
> let other = ([1 3 6] | dfr to-df);  
[5 6 6 6 8 8 8] | dfr to-df | dfr is-in $other
```

## dfr is-not-null

**version:** 0.61.0

### usage:

Creates mask where value is not null

### Signature

```
> dfr is-not-null
```

### Examples

Create mask where values are not null

```
> let s = ([5 6 0 8] | dfr to-df);  
  let res = ($s / $s);  
  $res | dfr is-not-null
```

## dfr is-null

**version:** 0.61.0

### usage:

Creates mask where value is null

### Signature

```
> dfr is-null
```

### Examples

Create mask where values are null

```
> let s = ([5 6 0 8] | dfr to-df);  
  let res = ($s / $s);  
  $res | dfr is-null
```

## dfr is-unique

**version:** 0.61.0

### usage:

Creates mask indicating unique values

### Signature

```
> dfr is-unique
```

### Examples

Create mask indicating unique values

```
|> [5 6 6 6 8 8 8] | dfr to-df | dfr is-unique
```

## dfr join

**version:** 0.61.0

### usage:

Joins a dataframe using columns as reference

### Signature

```
> dfr join (dataframe) --left --right --type --suffix
```

### Parameters

- **dataframe:** right dataframe to join
- **--left {table}:** left column names to perform join
- **--right {table}:** right column names to perform join
- **--type {string}:** type of join. Inner by default
- **--suffix {string}:** suffix for the columns of the right dataframe

## Examples

inner join dataframe

```
> let right = ([[a b c]; [1 2 5] [3 4 5] [5 6 6]] | dfr  
to-df);  
$right | dfr join $right -l [a b] -r [a b]
```

## dfr last

**version:** 0.61.0

**usage:**

Creates new dataframe with tail rows

## Signature

```
> dfr last (rows)
```

## Parameters

- **rows:** Number of rows for tail

## Examples

Create new dataframe with last rows

```
> [[a b]; [1 2] [3 4]] | dfr to-df | dfr last 1
```

## dfr list

**version:** 0.61.0

**usage:**

Lists stored dataframes

## Signature

```
> dfr list
```

## Examples

Creates a new dataframe and shows it in the dataframe list

```
> let test = ([[a b];[1 2] [3 4]] | dfr to-df);  
dfr list
```

## dfr melt

**version:** 0.61.0

### usage:

Unpivot a DataFrame from wide to long format

## Signature

```
> dfr melt --columns --values --variable-name --value-name
```

## Parameters

- `--columns {table}`: column names for melting
- `--values {table}`: column names used as value columns
- `--variable-name {string}`: optional name for variable column
- `--value-name {string}`: optional name for value column

## Examples

melt dataframe

```
> [[a b c d]; [x 1 4 a] [y 2 5 b] [z 3 6 c]] | dfr to-df  
| dfr melt -c [b c] -v [a d]
```

## dfr not

**version:** 0.61.0

**usage:**

Inverts boolean mask

**Signature**

```
> dfr not
```

**Examples**

Inverts boolean mask

```
> [true false true] | dfr to-df | dfr not
```

**dfr open**

**version:** 0.61.0

**usage:**

Opens csv, json or parquet file to create dataframe

**Signature**

```
> dfr open (file) --delimiter --no-header --infer-schema --  
skip-rows --columns
```

**Parameters**

- **file:** file path to load values from
- **--delimiter {string}:** file delimiter character. CSV file
- **--no-header:** Indicates if file doesn't have header. CSV file
- **--infer-schema {number}:** Number of rows to infer the schema of the file. CSV file
- **--skip-rows {number}:** Number of rows to skip from file. CSV file
- **--columns {list<string>}:** Columns to be selected from csv file. CSV and Parquet file

## Examples

Takes a file name and creates a dataframe

```
> dfr open test.csv
```

## dfr pivot

**version:** 0.61.0

### usage:

Performs a pivot operation on a groupby object

## Signature

```
> dfr pivot (pivot_column) (value_column) (operation)
```

## Parameters

- **pivot\_column:** pivot column to perform pivot
- **value\_column:** value column to perform pivot
- **operation:** aggregate operation

## Examples

Pivot a dataframe on b and aggregation on col c

```
> [[a b c]; [one x 1] [two y 2]] | dfr to-df | dfr group-  
by a | dfr pivot b c sum
```

## dfr rename-col

**version:** 0.61.0

### usage:

Rename a dataframe column

## Signature

```
> dfr rename-col (from) (to)
```

## Parameters

- **from**: column name to be renamed
- **to**: new column name

## Examples

Renames a dataframe column

```
> [[a b]; [1 2] [3 4]] | dfr to-df | dfr rename-col a a_-  
new
```

## dfr rename

**version:** 0.61.0

### usage:

Renames a series

## Signature

```
> dfr rename (name)
```

## Parameters

- **name**: new series name

## Examples

Renames a series

```
> [5 6 7 8] | dfr to-df | dfr rename new_name
```

## dfr replace-all

**version:** 0.61.0

### usage:

Replace all (sub)strings by a regex pattern

### Signature

```
> dfr replace-all --pattern --replace
```

### Parameters

- `--pattern {string}`: Regex pattern to be matched
- `--replace {string}`: replacing string

### Examples

Replaces string

```
> [abac abac abac] | dfr to-df | dfr replace-all -p a -  
r A
```

## dfr replace

**version:** 0.61.0

### usage:

Replace the leftmost (sub)string by a regex pattern

### Signature

```
> dfr replace --pattern --replace
```

### Parameters

- `--pattern {string}`: Regex pattern to be matched
- `--replace {string}`: replacing string

## Examples

Replaces string

```
> [abc abc abc] | dfr to-df | dfr replace -p ab -r AB
```

## dfr rolling

version: 0.61.0

### usage:

Rolling calculation for a series

## Signature

```
> dfr rolling (type) (window)
```

## Parameters

- type: rolling operation
- window: Window size for rolling

## Examples

Rolling sum for a series

```
> [1 2 3 4 5] | dfr to-df | dfr rolling sum 2 | dfr drop-nulls
```

Rolling max for a series

```
> [1 2 3 4 5] | dfr to-df | dfr rolling max 2 | dfr drop-nulls
```

## dfr sample

version: 0.61.0

**usage:**

Create sample dataframe

**Signature**

```
> dfr sample --n-rows --fraction --replace
```

**Parameters**

- `--n-rows {int}`: number of rows to be taken from dataframe
- `--fraction {number}`: fraction of dataframe to be taken
- `--replace`: sample with replace

**Examples**

Sample rows from dataframe

```
> [[a b]; [1 2] [3 4]] | dfr to-df | dfr sample -n 1
```

Shows sample row using fraction and replace

```
> [[a b]; [1 2] [3 4] [5 6]] | dfr to-df | dfr sample -  
f 0.5 -e
```

**dfr set-with-idx**

**version:** 0.61.0

**usage:**

Sets value in the given index

**Signature**

```
> dfr set-with-idx (value) --indices
```

## Parameters

- **value**: value to be inserted in series
- **--indices {any}**: list of indices indicating where to set the value

## Examples

Set value in selected rows from series

```
> let series = ([4 1 5 2 4 3] | dfr to-df);  
let indices = ([0 2] | dfr to-df);  
$series | dfr set-with-idx 6 -i $indices
```

## dfr set

**version:** 0.61.0

### usage:

Sets value where given mask is true

## Signature

```
> dfr set (value) --mask
```

## Parameters

- **value**: value to be inserted in series
- **--mask {any}**: mask indicating insertions

## Examples

Shifts the values by a given period

```
> let s = ([1 2 2 3 3] | dfr to-df | dfr shift 2);  
let mask = ($s | dfr is-null);  
$s | dfr set 0 --mask $mask
```

## dfr shape

**version:** 0.61.0

### usage:

Shows column and row size for a dataframe

### Signature

```
> dfr shape
```

### Examples

Shows row and column shape

```
> [[a b]; [1 2] [3 4]] | dfr to-df | dfr shape
```

## dfr shift

**version:** 0.61.0

### usage:

Shifts the values by a given period

### Signature

```
> dfr shift (period)
```

### Parameters

- **period:** shift period

### Examples

Shifts the values by a given period

```
> [1 2 2 3 3] | dfr to-df | dfr shift 2 | dfr drop-nulls
```

## dfr slice

**version:** 0.61.0

### usage:

Creates new dataframe from a slice of rows

### Signature

```
> dfr slice (offset) (size)
```

### Parameters

- **offset:** start of slice
- **size:** size of slice

### Examples

Create new dataframe from a slice of the rows

```
> [[a b]; [1 2] [3 4]] | dfr to-df | dfr slice 0 1
```

## dfr sort

**version:** 0.61.0

### usage:

Creates new sorted dataframe or series

### Signature

```
> dfr sort ...rest --reverse
```

### Parameters

- **...rest:** column names to sort dataframe
- **--reverse:** invert sort

## Examples

Create new sorted dataframe

```
> [[a b]; [3 4] [1 2]] | dfr to-df | dfr sort a
```

Create new sorted series

```
> [3 4 1 2] | dfr to-df | dfr sort
```

## dfr str-lengths

**version:** 0.61.0

### usage:

Get lengths of all strings

## Signature

```
> dfr str-lengths
```

## Examples

Returns string lengths

```
> [a ab abc] | dfr to-df | dfr str-lengths
```

## dfr str-slice

**version:** 0.61.0

### usage:

Slices the string from the start position until the selected length

## Signature

```
> dfr str-slice (start) --length
```

## Parameters

- **start**: start of slice
- **--length {int}**: optional length

## Examples

Creates slices from the strings

```
> [abcded abc321 abc123] | dfr to-df | dfr str-slice 1  
-l 2
```

## dfr strftime

version: 0.61.0

### usage:

Formats date based on string rule

## Signature

```
> dfr strftime (fmt)
```

## Parameters

- **fmt**: Format rule

## Examples

Formats date

```
> let dt = ('2020-08-04T16:39:18+00:00' | into datetime  
-z 'UTC');  
let df = ([dt dt] | dfr to-df);  
$df | dfr strftime "%Y/%m/%d"
```

## dfr take

version: 0.61.0

**usage:**

Creates new dataframe using the given indices

**Signature**

```
> dfr take (indices)
```

**Parameters**

- **indices**: list of indices used to take data

**Examples**

Takes selected rows from dataframe

```
> let df = ([a b]; [4 1] [5 2] [4 3]) | dfr to-df);  
let indices = ([0 2] | dfr to-df);  
$df | dfr take $indices
```

Takes selected rows from series

```
> let series = ([4 1 5 2 4 3] | dfr to-df);  
let indices = ([0 2] | dfr to-df);  
$series | dfr take $indices
```

**dfr to-csv**

version: 0.61.0

**usage:**

Saves dataframe to csv file

**Signature**

```
> dfr to-csv (file) --delimiter --no-header
```

## Parameters

- `file`: file path to save dataframe
- `--delimiter {string}`: file delimiter character
- `--no-header`: Indicates if file doesn't have header

## Examples

Saves dataframe to csv file

```
> [[a b]; [1 2] [3 4]] | dfr to-df | dfr to-csv test.csv
```

Saves dataframe to csv file using other delimiter

```
> [[a b]; [1 2] [3 4]] | dfr to-df | dfr to-csv test.csv  
-d '|'
```

## dfr to-df

**version:** 0.61.0

### usage:

Converts a List, Table or Dictionary into a dataframe

## Signature

```
> dfr to-df
```

## Examples

Takes a dictionary and creates a dataframe

```
> [[a b]; [1 2] [3 4]] | dfr to-df
```

Takes a list of tables and creates a dataframe

```
> [[1 2 a] [3 4 b] [5 6 c]] | dfr to-df
```

Takes a list and creates a dataframe

```
> [a b c] | dfr to-df
```

Takes a list of booleans and creates a dataframe

```
> [true true false] | dfr to-df
```

## dfr to-dummies

**version:** 0.61.0

### usage:

Creates a new dataframe with dummy variables

### Signature

```
> dfr to-dummies
```

### Examples

Create new dataframe with dummy variables from a dataframe

```
> [[a b]; [1 2] [3 4]] | dfr to-df | dfr to-dummies
```

Create new dataframe with dummy variables from a series

```
> [1 2 2 3 3] | dfr to-df | dfr to-dummies
```

## dfr to-lowercase

**version:** 0.61.0

### usage:

Lowercase the strings in the column

### Signature

```
> dfr to-lowercase
```

## Examples

Modifies strings to lowercase

```
> [Abc aBc abC] | dfr to-df | dfr to-lowercase
```

## dfr to-nu

version: 0.61.0

### usage:

Converts a section of the dataframe to Nushell Table

## Signature

```
> dfr to-nu --n-rows --tail
```

## Parameters

- `--n-rows {number}`: number of rows to be shown
- `--tail`: shows tail rows

## Examples

Shows head rows from dataframe

```
> [[a b]; [1 2] [3 4]] | dfr to-df | dfr to-nu
```

Shows tail rows from dataframe

```
> [[a b]; [1 2] [3 4] [5 6]] | dfr to-df | dfr to-nu -t  
-n 1
```

## dfr to-parquet

version: 0.61.0

**usage:**

Saves dataframe to parquet file

**Signature**

```
> dfr to-parquet (file)
```

**Parameters**

- file: file path to save dataframe

**Examples**

Saves dataframe to csv file

```
> [[a b]; [1 2] [3 4]] | dfr to-df | dfr to-parquet test.  
parquet
```

**dfr to-uppercase**

version: 0.61.0

**usage:**

Uppercase the strings in the column

**Signature**

```
> dfr to-uppercase
```

**Examples**

Modifies strings to uppercase

```
> [Abc aBc abC] | dfr to-df | dfr to-uppercase
```

**dfr unique**

version: 0.61.0

**usage:**

Returns unique values from a series

**Signature**

```
> dfr unique
```

**Examples**

Returns unique values from a series

```
> [2 2 2 2 2] | dfr to-df | dfr unique
```

**dfr value-counts**

**version:** 0.61.0

**usage:**

Returns a dataframe with the counts for unique values in series

**Signature**

```
> dfr value-counts
```

**Examples**

Calculates value counts

```
> [5 5 5 5 6 6] | dfr to-df | dfr value-counts
```

**dfr with-column**

**version:** 0.61.0

**usage:**

Adds a series to the dataframe

## Signature

```
> dfr with-column (series) --name
```

## Parameters

- **series**: series to be added
- **--name {string}**: column name

## Examples

Adds a series to the dataframe

```
> [[a b]; [1 2] [3 4]] | dfr to-df | dfr with-column ([5  
6] | dfr to-df) --name c
```

## do

**version:** 0.61.0

### usage:

Run a block

## Signature

```
> do (block) ...rest --ignore-errors
```

## Parameters

- **block**: the block to run
- **...rest**: the parameter(s) for the block
- **--ignore-errors**: ignore errors as the block runs

## Examples

Run the block

```
> do { echo hello }
```

Run the block and ignore errors

```
> do -i { thisisnotarealcommand }
```

Run the block, with a positional parameter

```
> do {|x| 100 + $x } 50
```

## drop

**version:** 0.61.0

### usage:

Remove the last number of rows or columns.

## Signature

```
> drop (rows)
```

## Parameters

- **rows:** starting from the back, the number of rows to remove

## Examples

Remove the last item of a list/table

```
> [0,1,2,3] | drop
```

Remove zero item of a list/table

```
> [0,1,2,3] | drop 0
```

Remove the last two items of a list/table

```
> [0,1,2,3] | drop 2
```

## drop column

**version:** 0.61.0

### usage:

Remove the last number of columns. If you want to remove columns by name, try 'reject'.

### Signature

```
> drop column (columns)
```

### Parameters

- **columns:** starting from the end, the number of columns to remove

## Examples

Remove the last column of a table

```
> echo [[lib, extension]; [nu-lib, rs] [nu-core, rb]] |  
drop column
```

## drop nth

**version:** 0.61.0

### usage:

Drop the selected rows.

### Signature

```
> drop nth (row number or row range) ...rest
```

## Parameters

- **row number or row range**: the number of the row to drop or a range to drop consecutive rows
- **...rest**: the number of the row to drop

## Examples

Drop the first, second, and third row

```
> [sam,sarah,2,3,4,5] | drop nth 0 1 2
```

Drop the first, second, and third row

```
> [0,1,2,3,4,5] | drop nth 0 1 2
```

Drop rows 0 2 4

```
> [0,1,2,3,4,5] | drop nth 0 2 4
```

Drop rows 2 0 4

```
> [0,1,2,3,4,5] | drop nth 2 0 4
```

Drop range rows from second to fourth

```
> echo [first second third fourth fifth] | drop nth (1.  
.3)
```

## du

**version:** 0.61.0

**usage:**

Find disk usage sizes of specified items.

## Signature

```
> du (path) --all --deref --exclude --max-depth --min-size
```

## Parameters

- **path**: starting directory
- **--all**: Output file sizes as well as directory sizes
- **--deref**: Dereference symlinks to their targets for size
- **--exclude {glob}**: Exclude these file names
- **--max-depth {int}**: Directory recursion limit
- **--min-size {int}**: Exclude files below this size

## Examples

Disk usage of the current directory

```
> du
```

## each

**version:** 0.61.0

### usage:

Run a block on each element of input

## Signature

```
> each (block) --keep-empty --numbered
```

## Parameters

- **block**: the block to run
- **--keep-empty**: keep empty result cells
- **--numbered**: iterate with an index

## Examples

Multiplies elements in list

```
> [1 2 3] | each { |it| 2 * $it }
```

Iterate over each element, keeping only values that succeed

```
> [1 2 3] | each { |it| if $it == 2 { echo "found 2!" } }
```

Iterate over each element, print the matching value and its index

```
> [1 2 3] | each -n { |it| if $it.item == 2 { echo $"found  
2 at ($it.index)!" } }
```

Iterate over each element, keeping all results

```
> [1 2 3] | each --keep-empty { |it| if $it == 2 { echo  
"found 2!" } }
```

## echo

**version:** 0.61.0

### usage:

Echo the arguments back to the user.

## Signature

```
> echo ...rest
```

## Parameters

- **...rest:** the values to echo

## Examples

Put a hello message in the pipeline

```
> echo 'hello'
```

Print the value of the special '\$nu' variable

```
> echo $nu
```

## empty?

**version:** 0.61.0

### usage:

Check for empty values.

## Signature

```
> empty? ...rest
```

## Parameters

- **...rest:** the names of the columns to check emptiness

## Examples

Check if a string is empty

```
> '' | empty?
```

Check if a list is empty

```
> [] | empty?
```

Check if more than one column are empty

```
> [[meal size]; [arepa small] [taco '']] | empty? meal  
size
```

## enter

**version:** 0.61.0

### usage:

Enters a new shell at the given path.

## Signature

```
> enter (path)
```

## Parameters

- **path:** the path to enter as a new shell

## Examples

Enter a new shell at path ‘../dir-foo’

```
> enter ../dir-foo
```

## env

**version:** 0.61.0

### usage:

Display current environment variables

## Signature

```
> env
```

## Examples

Display current path environment variable

```
> env | where name == PATH
```

Check whether the env variable MY\_ENV\_ABC exists

```
> env | any? name == MY_ENV_ABC
```

Another way to check whether the env variable PATH exists

```
> 'PATH' in (env).name
```

## error make

**version:** 0.61.0

### usage:

Create an error.

### Signature

```
> error make (error_struct)
```

### Parameters

- `error_struct`: the error to create

## Examples

Create a custom error for a custom command

```
> def foo [x] {  
  let span = (metadata $x).span;  
  error make {msg: "this is fishy", label: {text: "fish  
right here", start: $span.start, end: $span.end } }  
}
```

Create a simple custom error for a custom command

```
> def foo [x] {  
  error make {msg: "this is fishy"}  
}
```

## every

**version:** 0.61.0

### usage:

Show (or skip) every n-th row, starting from the first one.

## Signature

```
> every (stride) --skip
```

## Parameters

- **stride:** how many rows to skip between (and including) each row returned
- **--skip:** skip the rows that would be returned, instead of selecting them

## Examples

Get every second row

```
> [1 2 3 4 5] | every 2
```

Skip every second row

```
> [1 2 3 4 5] | every 2 --skip
```

## exec

**version:** 0.61.0

### usage:

Execute a command, replacing the current process.

## Signature

```
> exec (command) ...rest
```

## Parameters

- **command**: the command to execute
- **...rest**: any additional arguments for the command

## Examples

Execute external ‘ps aux’ tool

```
> exec ps aux
```

Execute ‘nautilus’

```
> exec nautilus
```

## exit

**version:** 0.61.0

### usage:

Exit a Nu shell or exit Nu entirely.

## Signature

```
> exit (exit_code) --now
```

## Parameters

- **exit\_code**: Exit code to return immediately with
- **--now**: Exit out of all shells immediately (exiting Nu)

## Examples

Exit the current shell

```
> exit
```

Exit all shells (exiting Nu)

```
> exit --now
```

## export

**version:** 0.61.0

### usage:

Export custom commands or environment variables from a module.

## Signature

```
> export
```

## Examples

Export a definition from a module

```
> module utils { export def my-command [] { "hello" } };  
use utils my-command; my-command
```

## export alias

**version:** 0.61.0

### usage:

Define an alias and export it from a module

## Signature

```
> export alias (name) (initial_value)
```

## Parameters

- **name:** name of the alias
- **initial\_value:** equals sign followed by value

## Examples

export an alias of ll to ls -l, from a module

```
> export alias ll = ls -l
```

## export def-env

**version:** 0.61.0

### usage:

Define a custom command that participates in the environment and export it from a module

## Signature

```
> export def-env (name) (params) (block)
```

## Parameters

- **name:** definition name
- **params:** parameters
- **block:** body of the definition

## Examples

Define a custom command that participates in the environment in a module and call it

```
> module foo { export def-env bar [] { let-env FOO_BAR  
= "BAZ" } }; use foo bar; bar; $env.FOO_BAR
```

## export def

**version:** 0.61.0

**usage:**

Define a custom command and export it from a module

**Signature**

```
> export def (name) (params) (block)
```

**Parameters**

- **name:** definition name
- **params:** parameters
- **block:** body of the definition

**Examples**

Define a custom command in a module and call it

```
> module spam { export def foo [] { "foo" } }; use spam  
foo; foo
```

**export env**

**version:** 0.61.0

**usage:**

Export a block from a module that will be evaluated as an environment variable when imported.

**Signature**

```
> export env (name) (block)
```

**Parameters**

- **name:** name of the environment variable
- **block:** body of the environment variable definition

## Examples

Import and evaluate environment variable from a module

```
> module foo { export env FOO_ENV { "BAZ" } }; use foo
FOO_ENV; $env.FOO_ENV
```

## export extern

**version:** 0.61.0

### usage:

Define an extern and export it from a module

## Signature

```
> export extern (def_name) (params)
```

## Parameters

- **def\_name:** definition name
- **params:** parameters

## Examples

Export the signature for an external command

```
> export extern echo [text: string]
```

## extern

**version:** 0.61.0

### usage:

Define a signature for an external command

## Signature

```
> extern (def_name) (params)
```

## Parameters

- `def_name`: definition name
- `params`: parameters

## Examples

Write a signature for an external command

```
> extern echo [text: string]
```

## fetch

version: 0.61.0

### usage:

Fetch the contents from a URL.

## Signature

```
> fetch (URL) --user --password --timeout --headers --raw
```

## Parameters

- `URL`: the URL to fetch the contents from
- `--user {any}`: the username when authenticating
- `--password {any}`: the password when authenticating
- `--timeout {int}`: timeout period in seconds
- `--headers {any}`: custom headers you want to add
- `--raw`: fetch contents as text rather than a table

## Examples

Fetch content from url.com

```
> fetch url.com
```

Fetch content from url.com, with username and password

```
> fetch -u myuser -p mypass url.com
```

Fetch content from url.com, with custom header

```
> fetch -H [my-header-key my-header-value] url.com
```

## find

**version:** 0.61.0

### usage:

Searches terms in the input or for elements of the input that satisfies the predicate.

## Signature

```
> find ...rest --predicate --regex --insensitive --multiline  
--dotall --invert
```

## Parameters

- **...rest:** terms to search
- **--predicate {block}:** the predicate to satisfy
- **--regex {string}:** regex to match with
- **--insensitive:** case-insensitive search for regex (?i)
- **--multiline:** multi-line mode: ^ and \$ match begin/end of line for regex (?m)
- **--dotall:** dotall mode: allow a dot . to match newline character \n for regex (?s)
- **--invert:** invert the match

## Examples

Search for multiple terms in a command output

```
> ls | find toml md sh
```

Search for a term in a string

```
> echo Cargo.toml | find toml
```

Search a number or a file size in a list of numbers

```
> [1 5 3kb 4 3Mb] | find 5 3kb
```

Search a char in a list of string

```
> [moe larry curly] | find l
```

Find odd values

```
> [2 4 3 6 5 8] | find --predicate { |it| ($it mod 2) ==  
1 }
```

Find if a service is not running

```
> [[version patch]; [0.1.0 false] [0.1.1 true] [0.2.0 false]]  
| find -p { |it| $it.patch }
```

Find using regex

```
> [abc bde arc abf] | find --regex "ab"
```

Find using regex case insensitive

```
> [aBc bde Arc abf] | find --regex "ab" -i
```

Find value in records

```
> [[version name]; [0.1.0 nushell] [0.1.1 fish] [0.2.0  
zsh]] | find -r "nu"
```

## first

**version:** 0.61.0

### usage:

Show only the first number of rows.

## Signature

```
> first (rows)
```

## Parameters

- **rows:** starting from the front, the number of rows to return

## Examples

Return the first item of a list/table

```
> [1 2 3] | first
```

Return the first 2 items of a list/table

```
> [1 2 3] | first 2
```

## flatten

**version:** 0.61.0

### usage:

Flatten the table.

## Signature

```
> flatten ...rest
```

## Parameters

- `...rest`: optionally flatten data by column

## Examples

flatten a table

```
> [[N, u, s, h, e, l, l]] | flatten
```

flatten a table, get the first item

```
> [[N, u, s, h, e, l, l]] | flatten | first
```

flatten a column having a nested table

```
> [[origin, people]; [Ecuador, ([[name, meal]; ['Andres',  
'arepa']])] ] | flatten | get meal
```

restrict the flattening by passing column names

```
> [[origin, crate, versions]; [World, ([[name]; ['nu-cli']])  
, ['0.21', '0.22']] ] | flatten versions | last | get versions
```

Flatten inner table

```
> { a: b, d: [ 1 2 3 4 ], e: [ 4 3 ] } | flatten
```

## fmt

**version:** 0.61.0

### usage:

Format a number

## Signature

```
> fmt
```

## Examples

Get a record containing multiple formats for the number 42

```
> 42 | fmt
```

## for

**version:** 0.61.0

### usage:

Loop over a range

## Signature

```
> for (var_name) (range) (block) --numbered
```

## Parameters

- **var\_name:** name of the looping variable
- **range:** range of the loop
- **block:** the block to run
- **--numbered:** returned a numbered item (\$it.index and \$it.item)

## Examples

Echo the square of each integer

```
> for x in [1 2 3] { $x * $x }
```

Work with elements of a range

```
> for $x in 1..3 { $x }
```

Number each item and echo a message

```
> for $it in ['bob' 'fred'] --numbered { "$($it.index)  
is ($it.item)" }
```

## format

**version:** 0.61.0

### usage:

Format columns into a string using a simple pattern.

## Signature

```
> format (pattern)
```

## Parameters

- **pattern:** the pattern to output. e.g.) “{foo}: {bar}”

## Examples

Print filenames with their sizes

```
> ls | format '{name}: {size}'
```

Print elements from some columns of a table

```
> echo [[col1, col2]; [v1, v2] [v3, v4]] | format '{col2}'
```

## from

**version:** 0.61.0

**usage:**

Parse a string or binary data into structured data

**Signature**

```
> from
```

**from csv**

**version:** 0.61.0

**usage:**

Parse text as .csv and create table.

**Signature**

```
> from csv --separator --noheaders
```

**Parameters**

- **--separator {string}:** a character to separate columns, defaults to ‘,’
- **--noheaders:** don’t treat the first row as column names

**Examples**

Convert comma-separated data to a table

```
> open data.txt | from csv
```

Convert comma-separated data to a table, ignoring headers

```
> open data.txt | from csv --noheaders
```

Convert comma-separated data to a table, ignoring headers

```
> open data.txt | from csv -n
```

Convert semicolon-separated data to a table

```
> open data.txt | from csv --separator ';' 
```

## from eml

**version:** 0.61.0

### usage:

Parse text as .eml and create table.

## Signature

```
> from eml --preview-body
```

## Parameters

- `--preview-body {int}`: How many bytes of the body to preview

## Examples

Convert eml structured data into table

```
> 'From: test@email.com
Subject: Welcome
To: someone@somewhere.com

Test' | from eml
```

Convert eml structured data into table

```
> 'From: test@email.com
Subject: Welcome
To: someone@somewhere.com

Test' | from eml -b 1
```

## from ics

**version:** 0.61.0

**usage:**

Parse text as .ics and create table.

**Signature**

```
> from ics
```

**Examples**

Converts ics formatted string to table

```
> 'BEGIN:VCALENDAR  
END:VCALENDAR' | from ics
```

**from ini**

**version:** 0.61.0

**usage:**

Parse text as .ini and create table

**Signature**

```
> from ini
```

**Examples**

Converts ini formatted string to table

```
> '[foo]  
a=1  
b=2' | from ini
```

**from json**

**version:** 0.61.0

**usage:**

Convert from json to structured data

**Signature**

```
> from json --objects
```

**Parameters**

- `--objects`: treat each line as a separate value

**Examples**

Converts json formatted string to table

```
> '{ "a": 1 }' | from json
```

Converts json formatted string to table

```
> '{ "a": 1, "b": [1, 2] }' | from json
```

**from nuon**

**version:** 0.61.0

**usage:**

Convert from nuon to structured data

**Signature**

```
> from nuon
```

**Examples**

Converts nuon formatted string to table

```
> '{ a:1 }' | from nuon
```

Converts nuon formatted string to table

```
> '{ a:1, b: [1, 2] }' | from nuon
```

## from ods

**version:** 0.61.0

### usage:

Parse OpenDocument Spreadsheet(.ods) data and create table.

## Signature

```
> from ods --sheets
```

## Parameters

- `--sheets {list<string>}`: Only convert specified sheets

## Examples

Convert binary .ods data to a table

```
> open test.txt | from ods
```

Convert binary .ods data to a table, specifying the tables

```
> open test.txt | from ods -s [Spreadsheet1]
```

## from ssv

**version:** 0.61.0

### usage:

Parse text as space-separated values and create a table. The default minimum number of spaces counted as a separator is 2.

## Signature

```
> from ssv --noheaders --aligned-columns --minimum-spaces
```

## Parameters

- `--noheaders`: don't treat the first row as column names
- `--aligned-columns`: assume columns are aligned
- `--minimum-spaces {int}`: the minimum spaces to separate columns

## Examples

Converts ssv formatted string to table

```
> 'FOO  BAR
1  2' | from ssv
```

Converts ssv formatted string to table but not treating the first row as column names

```
> 'FOO  BAR
1  2' | from ssv -n
```

## from toml

version: 0.61.0

### usage:

Parse text as .toml and create table.

## Signature

```
> from toml
```

## Examples

Converts toml formatted string to table

```
> 'a = 1' | from toml
```

Converts toml formatted string to table

```
> 'a = 1
b = [1, 2]' | from toml
```

## from tsv

**version:** 0.61.0

### usage:

Parse text as .tsv and create table.

## Signature

```
> from tsv --noheaders
```

## Parameters

- **--noheaders:** don't treat the first row as column names

## Examples

Create a tsv file with header columns and open it

```
> echo $'c1(char tab)c2(char tab)c3(char nl)1(char tab)
2(char tab)3' | save tsv-data | open tsv-data | from tsv
```

Create a tsv file without header columns and open it

```
> echo $'a1(char tab)b1(char tab)c1(char nl)a2(char tab)
b2(char tab)c2' | save tsv-data | open tsv-data | from
tsv -n
```

## from url

**version:** 0.61.0

**usage:**

Parse url-encoded string as a table.

**Signature**

> from url

**Examples**

Convert url encoded string into a table

```
> 'bread=baguette&cheese=comt%C3%A9&meat=ham&fat=butter'
| from url
```

**from vcf**

version: 0.61.0

**usage:**

Parse text as .vcf and create table.

**Signature**

> from vcf

**Examples**

Converts ics formatted string to table

```
> 'BEGIN:VCARD
N:Foo
FN:Bar
EMAIL:foo@bar.com
END:VCARD' | from vcf
```

**from xlsx**

version: 0.61.0

**usage:**

Parse binary Excel(.xlsx) data and create table.

**Signature**

```
> from xlsx --sheets
```

**Parameters**

- `--sheets {list<string>}`: Only convert specified sheets

**Examples**

Convert binary .xlsx data to a table

```
> open test.txt | from xlsx
```

Convert binary .xlsx data to a table, specifying the tables

```
> open test.txt | from xlsx -s [Spreadsheet1]
```

**from xml**

**version:** 0.61.0

**usage:**

Parse text as .xml and create table.

**Signature**

```
> from xml
```

**Examples**

Converts xml formatted string to table

```
> '<?xml version="1.0" encoding="UTF-8"?>
<note>
<remember>Event</remember>
```

```
</note>' | from xml
```

## from yaml

**version:** 0.61.0

### usage:

Parse text as .yaml/.yml and create table.

### Signature

```
> from yaml
```

### Examples

Converts yaml formatted string to table

```
> 'a: 1' | from yaml
```

Converts yaml formatted string to table

```
> '[ a: 1, b: [1, 2] ]' | from yaml
```

## from yml

**version:** 0.61.0

### usage:

Parse text as .yaml/.yml and create table.

### Signature

```
> from yml
```

## Examples

Converts yaml formatted string to table

```
> 'a: 1' | from yaml
```

Converts yaml formatted string to table

```
> '[ a: 1, b: [1, 2] ]' | from yaml
```

## g

**version:** 0.61.0

### usage:

Switch to a given shell.

## Signature

```
> g (shell_number)
```

## Parameters

- **shell\_number:** shell number to change to

## Examples

Make two directories and enter new shells for them, use **g** to jump to the specific shell

```
> mkdir foo bar; enter foo; enter ../bar; g 1
```

Use **shells** to show all the opened shells and run **g 2** to jump to the third one

```
> shells; g 2
```

## get

**version:** 0.61.0

### usage:

Extract data using a cell path.

## Signature

```
> get (cell_path) ...rest --ignore-errors
```

## Parameters

- **cell\_path:** the cell path to the data
- **...rest:** additional cell paths
- **--ignore-errors:** return nothing if path can't be found

## Examples

Extract the name of files as a list

```
> ls | get name
```

Extract the name of the 3rd entry of a file list

```
> ls | get name.2
```

Extract the name of the 3rd entry of a file list (alternative)

```
> ls | get 2.name
```

Extract the cpu list from the sys information record

```
> sys | get cpu
```

## glob

**version:** 0.61.0

**usage:**

Creates a list of files and/or folders based on the glob pattern provided.

**Signature**

```
> glob (glob) --depth
```

**Parameters**

- **glob**: the glob expression
- **--depth {int}**: directory depth to search

**Examples**

Search for \*.rs files

```
> glob *.rs
```

Search for \_\_.rs and \_\_.toml files recursively up to 2 folders deep

```
> glob **/*.{rs,toml} --depth 2
```

Search for files and folders that begin with uppercase C and lowercase c

```
> glob "[Cc]*"
```

Search for files and folders like abc or xyz substituting a character for ?

```
> glob "{a?c,x?z}"
```

A case-insensitive search for files and folders that begin with c

```
> glob "(?i)c*"
```

Search for files for folders that do not begin with c, C, b, M, or s

```
> glob "[!cCbMs]*"
```

Search for files or folders with 3 a's in a row in the name

```
> glob <a*.3>
```

Search for files or folders with only a, b, c, or d in the file name between 1 and 10 times

```
> glob <[a-d]:1,10>
```

## grid

**version:** 0.61.0

### usage:

Renders the output to a textual terminal grid.

## Signature

```
> grid --width --color --separator
```

## Parameters

- `--width {int}`: number of terminal columns wide (not output columns)
- `--color`: draw output with color
- `--separator {string}`: character to separate grid with

## Examples

Render a simple list to a grid

```
> [1 2 3 a b c] | grid
```

The above example is the same as:

```
> [1 2 3 a b c] | wrap name | grid
```

Render a record to a grid

```
> {name: 'foo', b: 1, c: 2} | grid
```

Render a list of records to a grid

```
> [{name: 'A', v: 1} {name: 'B', v: 2} {name: 'C', v: 3}]  
| grid
```

Render a table with ‘name’ column in it to a grid

```
> [[name patch]; [0.1.0 false] [0.1.1 true] [0.2.0 false]]  
| grid
```

## group-by

version: 0.61.0

### usage:

Create a new table grouped.

### Signature

```
> group-by (grouper)
```

### Parameters

- **grouper**: the grouper value to use

### Examples

group items by column named “type”

```
> ls | group-by type
```

you can also group by raw values by leaving out the argument

```
> echo ['1' '3' '1' '3' '2' '1' '1'] | group-by
```

## group

**version:** 0.61.0

### usage:

Groups input into groups of `group_size`.

## Signature

```
> group (group_size)
```

## Parameters

- `group_size`: the size of each group

## Examples

Group the a list by pairs

```
> echo [1 2 3 4] | group 2
```

## hash

**version:** 0.61.0

### usage:

Apply hash function.

## Signature

```
> hash
```

## hash base64

**version:** 0.61.0

**usage:**

base64 encode or decode a value

**Signature**

```
> hash base64 ...rest --character-set --encode --decode
```

**Parameters**

- `...rest`: optionally base64 encode / decode data by column paths
- `--character-set {string}`: specify the character rules for encoding the input. Valid values are 'standard', 'standard-no-padding', 'url-safe', 'url-safe-no-padding', 'binhex', 'bcrypt', 'crypt'
- `--encode`: encode the input as base64. This is the default behavior if not specified.
- `--decode`: decode the input from base64

**Examples**

Base64 encode a string with default settings

```
> echo 'username:password' | hash base64
```

Base64 encode a string with the binhex character set

```
> echo 'username:password' | hash base64 --character-set  
binhex --encode
```

Base64 decode a value

```
> echo 'dXN1cm5hbWU6cGFzc3dvcmQ=' | hash base64 --decode
```

**hash md5**

**version:** 0.61.0

**usage:**

Hash a value using the md5 hash algorithm

**Signature**

```
> hash md5 ...rest
```

**Parameters**

- ...rest: optionally md5 hash data by cell path

**Examples**

md5 encode a string

```
> echo 'abcdefghijklmnopqrstuvwxy' | hash md5
```

md5 encode a file

```
> open ./nu_0_24_1_windows.zip | hash md5
```

**hash sha256**

**version:** 0.61.0

**usage:**

Hash a value using the sha256 hash algorithm

**Signature**

```
> hash sha256 ...rest
```

**Parameters**

- ...rest: optionally sha256 hash data by cell path

## Examples

sha256 encode a string

```
> echo 'abcdefghijklmnopqrstuvwxyz' | hash sha256
```

sha256 encode a file

```
> open ./nu_0_24_1_windows.zip | hash sha256
```

## headers

**version:** 0.61.0

### usage:

Use the first row of the table as column names.

## Signature

```
> headers
```

## Examples

Returns headers from table

```
> "a b c|1 2 3" | split row "|" | split column " " | headers
```

Don't panic on rows with different headers

```
> "a b c|1 2 3|1 2 3 4" | split row "|" | split column  
" " | headers
```

## help

**version:** 0.61.0

### usage:

Display help information about commands.

## Signature

```
> help ...rest --find
```

## Parameters

- `...rest`: the name of command to get help on
- `--find {string}`: string to find in command names, usage, and search terms

## Examples

show all commands and sub-commands

```
> help commands
```

generate documentation

```
> help generate_docs
```

show help for single command

```
> help match
```

show help for single sub-command

```
> help str lpad
```

search for string in command names, usage and search terms

```
> help --find char
```

## hide

**version:** 0.61.0

### usage:

Hide symbols in the current scope

## Signature

```
> hide (pattern)
```

## Parameters

- **pattern**: import pattern

## Examples

Hide the alias just defined

```
> alias lll = ls -l; hide lll
```

Hide a custom command

```
> def say-hi [] { echo 'Hi!' }; hide say-hi
```

Hide an environment variable

```
> let-env HZ_ENV_ABC = 1; hide HZ_ENV_ABC; 'HZ_ENV_ABC'  
in (env).name
```

## history

**version:** 0.61.0

### usage:

Get the command history

## Signature

```
> history --clear
```

## Parameters

- **--clear**: Clears out the history entries

## Examples

Get current history length

```
> history | length
```

Show last 5 commands you have ran

```
> history | last 5
```

Search all the commands from history that contains 'cargo'

```
> history | wrap cmd | where cmd =~ cargo
```

## if

**version:** 0.61.0

**usage:**

Conditionally run a block.

## Signature

```
> if (cond) (then_block) (else_expression)
```

## Parameters

- **cond:** condition to check
- **then\_block:** block to run if check succeeds
- **else\_expression:** expression or block to run if check fails

## Examples

Output a value if a condition matches, otherwise return nothing

```
> if 2 < 3 { 'yes!' }
```

Output a value if a condition matches, else return another value

```
> if 5 < 3 { 'yes!' } else { 'no!' }
```

Chain multiple if's together

```
> if 5 < 3 { 'yes!' } else if 4 < 5 { 'no!' } else { 'okay!' }
```

## ignore

**version:** 0.61.0

### usage:

Ignore the output of the previous command in the pipeline

## Signature

```
> ignore
```

## Examples

Ignore the output of an echo command

```
> echo done | ignore
```

## input

**version:** 0.61.0

### usage:

Get input from the user.

## Signature

```
> input (prompt) --bytes-until --suppress-output
```

## Parameters

- `prompt`: prompt to show the user
- `--bytes-until {string}`: read bytes (not text) until a stop byte
- `--suppress-output`: don't print keystroke values

## Examples

Get input from the user, and assign to a variable

```
> let user-input = (input)
```

## insert

**version:** 0.61.0

### usage:

Insert a new column.

## Signature

```
> insert (field) (new value)
```

## Parameters

- `field`: the name of the column to insert
- `new value`: the new value to give the cell(s)

## Examples

Insert a new value

```
> echo {'name': 'nu', 'stars': 5} | insert alias 'Nushell'
```

## into

**version:** 0.61.0

**usage:**

Commands to convert data from one type to another.

**Signature**

```
> into
```

**into binary**

**version:** 0.61.0

**usage:**

Convert value to a binary primitive

**Signature**

```
> into binary ...rest
```

**Parameters**

- **...rest:** column paths to convert to binary (for table input)

**Examples**

convert string to a nushell binary primitive

```
> 'This is a string that is exactly 52 characters long.'
  | into binary
```

convert a number to a nushell binary primitive

```
> 1 | into binary
```

convert a boolean to a nushell binary primitive

```
> true | into binary
```

convert a filesize to a nushell binary primitive

```
> ls | where name == LICENSE | get size | into binary
```

convert a filepath to a nushell binary primitive

```
> ls | where name == LICENSE | get name | path expand |  
into binary
```

convert a decimal to a nushell binary primitive

```
> 1.234 | into binary
```

## into bool

**version:** 0.61.0

### usage:

Convert value to boolean

### Signature

```
> into bool ...rest
```

### Parameters

- **...rest:** column paths to convert to boolean (for table input)

### Examples

Convert value to boolean in table

```
> echo [[value]; ['false'] ['1'] [0] [1.0] [true]] | into  
bool value
```

Convert bool to boolean

```
> true | into bool
```

convert integer to boolean

```
> 1 | into bool
```

convert decimal string to boolean

```
> '0.0' | into bool
```

convert string to boolean

```
> 'true' | into bool
```

## into datetime

**version:** 0.61.0

### usage:

Convert text into a datetime

### Signature

```
> into datetime ...rest --list --timezone --offset --format
```

### Parameters

- **...rest:** optionally convert text into datetime by column paths
- **--list:** lists strftime cheatsheet
- **--timezone {string}:** Specify timezone if the input is timestamp, like 'UTC/u' or 'LOCAL/l'
- **--offset {int}:** Specify timezone by offset if the input is timestamp, like '+8', '-4', prior than timezone
- **--format {string}:** Specify date and time formatting

### Examples

Convert to datetime

```
> '16.11.1984 8:00 am +0000' | into datetime
```

Convert to datetime

```
> '2020-08-04T16:39:18+00:00' | into datetime
```

Convert to datetime using a custom format

```
> '20200904_163918+0000' | into datetime -f '%Y%m%d_%H%M%S%z'
```

Convert timestamp (no larger than  $8e+12$ ) to datetime using a specified timezone

```
> '1614434140' | into datetime -z 'UTC'
```

Convert timestamp (no larger than  $8e+12$ ) to datetime using a specified timezone offset (between -12 and 12)

```
> '1614434140' | into datetime -o +9
```

## into decimal

**version:** 0.61.0

### usage:

Convert text into a decimal

### Signature

```
> into decimal ...rest
```

### Parameters

- `...rest`: optionally convert text into decimal by column paths

### Examples

Convert string to integer in table

```
> [[num]; ['5.01']] | into decimal num
```

Convert string to integer

```
> '1.345' | into decimal
```

Convert decimal to integer

```
> '-5.9' | into decimal
```

## into duration

**version:** 0.61.0

### usage:

Convert value to duration

## Signature

```
> into duration ...rest
```

## Parameters

- `...rest`: column paths to convert to duration (for table input)

## Examples

Convert string to duration in table

```
> echo [[value]; ['1sec'] ['2min'] ['3hr'] ['4day'] ['5wk']]  
| into duration value
```

Convert string to duration

```
> '7min' | into duration
```

## into filesize

version: 0.61.0

### usage:

Convert value to filesize

### Signature

```
> into filesize ...rest
```

### Parameters

- `...rest`: column paths to convert to filesize (for table input)

### Examples

Convert string to filesize in table

```
> [[bytes]; ['5'] [3.2] [4] [2kb]] | into filesize bytes
```

Convert string to filesize

```
> '2' | into filesize
```

Convert decimal to filesize

```
> 8.3 | into filesize
```

Convert int to filesize

```
> 5 | into filesize
```

Convert file size to filesize

```
> 4KB | into filesize
```

## into int

version: 0.61.0

**usage:**

Convert value to integer

**Signature**

```
> into int ...rest --radix
```

**Parameters**

- `...rest`: column paths to convert to int (for table input)
- `--radix {number}`: radix of integer

**Examples**

Convert string to integer in table

```
> echo [[num]; ['-5'] [4] [1.5]] | into int num
```

Convert string to integer

```
> '2' | into int
```

Convert decimal to integer

```
> 5.9 | into int
```

Convert decimal string to integer

```
> '5.9' | into int
```

Convert file size to integer

```
> 4KB | into int
```

Convert bool to integer

```
> [false, true] | into int
```

Convert to integer from binary

```
> '1101' | into int -r 2
```

Convert to integer from hex

```
> 'FF' | into int -r 16
```

## into string

**version:** 0.61.0

### usage:

Convert value to string

### Signature

```
> into string ...rest --decimals
```

### Parameters

- `...rest`: column paths to convert to string (for table input)
- `--decimals {int}`: decimal digits to which to round

### Examples

convert decimal to string and round to nearest integer

```
> 1.7 | into string -d 0
```

convert decimal to string

```
> 1.7 | into string -d 1
```

convert decimal to string and limit to 2 decimals

```
> 1.734 | into string -d 2
```

try to convert decimal to string and provide negative decimal points

```
> 1.734 | into string -d -2
```

convert decimal to string

```
> 4.3 | into string
```

convert string to string

```
> '1234' | into string
```

convert boolean to string

```
> true | into string
```

convert date to string

```
> date now | into string
```

convert filepath to string

```
> ls Cargo.toml | get name | into string
```

convert filesize to string

```
> ls Cargo.toml | get size | into string
```

## keep

**version:** 0.61.0

**usage:**

Deprecated command

## Signature

```
> keep
```

## keep until

**version:** 0.61.0

### **usage:**

Deprecated command

### **Signature**

> keep until

## keep while

**version:** 0.61.0

### **usage:**

Deprecated command

### **Signature**

> keep while

## keybindings

**version:** 0.61.0

### **usage:**

Keybindings related commands

### **Signature**

> keybindings

## keybindings default

**version:** 0.61.0

**usage:**

List default keybindings

**Signature**

```
> keybindings default
```

**Examples**

Get list with default keybindings

```
| > keybindings default
```

**keybindings list**

**version:** 0.61.0

**usage:**

List available options that can be used to create keybindings

**Signature**

```
> keybindings list --modifiers --keycodes --modes --events -  
-edits
```

**Parameters**

- **--modifiers:** list of modifiers
- **--keycodes:** list of keycodes
- **--modes:** list of edit modes
- **--events:** list of reedline event
- **--edits:** list of edit commands

## Examples

Get list of key modifiers

```
> keybindings list -m
```

Get list of reedline events and edit commands

```
> keybindings list -e -d
```

Get list with all the available options

```
> keybindings list
```

## keybindings listen

**version:** 0.61.0

### usage:

Get input from the user.

## Signature

```
> keybindings listen
```

## Examples

Type and see key event codes

```
> keybindings listen
```

## kill

**version:** 0.61.0

### usage:

Kill a process using the process id.

## Signature

```
> kill (pid) ...rest --force --quiet --signal
```

## Parameters

- **pid**: process id of process that is to be killed
- **...rest**: rest of processes to kill
- **--force**: forcefully kill the process
- **--quiet**: won't print anything to the console
- **--signal {int}**: signal decimal number to be sent instead of the default 15 (unsupported on Windows)

## Examples

Kill the pid using the most memory

```
> ps | sort-by mem | last | kill $in.pid
```

Force kill a given pid

```
> kill --force 12345
```

Send INT signal

```
> kill -s 2 12345
```

## last

**version:** 0.61.0

**usage:**

Show only the last number of rows.

## Signature

```
> last (rows)
```

## Parameters

- **rows:** starting from the back, the number of rows to return

## Examples

Get the last 2 items

```
> [1,2,3] | last 2
```

Get the last item

```
> [1,2,3] | last
```

## length

**version:** 0.61.0

### usage:

Count the number of elements in the input.

## Signature

```
> length --column
```

## Parameters

- **--column:** Show the number of columns in a table

## Examples

Count the number of entries in a list

```
> echo [1 2 3 4 5] | length
```

Count the number of columns in the calendar table

```
> cal | length -c
```

## let-env

**version:** 0.61.0

### usage:

Create an environment variable and give it a value.

### Signature

```
> let-env (var_name) (initial_value)
```

### Parameters

- **var\_name:** variable name
- **initial\_value:** equals sign followed by value

### Examples

Create an environment variable and display it

```
> let-env MY_ENV_VAR = 1; $env.MY_ENV_VAR
```

## let

**version:** 0.61.0

### usage:

Create a variable and give it a value.

### Signature

```
> let (var_name) (initial_value)
```

### Parameters

- **var\_name:** variable name
- **initial\_value:** equals sign followed by value

## Examples

Set a variable to a value

```
> let x = 10
```

Set a variable to the result of an expression

```
> let x = 10 + 100
```

Set a variable based on the condition

```
> let x = if false { -1 } else { 1 }
```

## lines

**version:** 0.61.0

**usage:**

Converts input to lines

## Signature

```
> lines --skip-empty
```

## Parameters

- `--skip-empty`: skip empty lines

## Examples

Split multi-line string into lines

```
> echo $'two(char nl)lines' | lines
```

## load-env

**version:** 0.61.0

**usage:**

Loads an environment update from a record.

**Signature**

```
> load-env (update)
```

**Parameters**

- **update:** the record to use for updates

**Examples**

Load variables from an input stream

```
> {NAME: ABE, AGE: UNKNOWN} | load-env; echo $env.NAME
```

Load variables from an argument

```
> load-env {NAME: ABE, AGE: UNKNOWN}; echo $env.NAME
```

**ls**

**version:** 0.61.0

**usage:**

List the files in a directory.

**Signature**

```
> ls (pattern) --all --long --short-names --full-paths --du
```

**Parameters**

- **pattern:** the glob pattern to use
- **--all:** Show hidden files
- **--long:** List all available columns for each entry

- **--short-names:** Only print the file names and not the path
- **--full-paths:** display paths as absolute paths
- **--du:** Display the apparent directory size in place of the directory metadata size

## Examples

List all files in the current directory

```
> ls
```

List all files in a subdirectory

```
> ls subdir
```

List all rust files

```
> ls *.rs
```

List all files and directories whose name do not contain 'bar'

```
> ls -s | where name !~ bar
```

List all dirs with full path name in your home directory

```
> ls -f ~ | where type == dir
```

List all dirs in your home directory which have not been modified in 7 days

```
> ls -s ~ | where type == dir && modified < ((date now) - 7day)
```

## match

**version:** 0.61.0

**usage:**

Deprecated command

**Signature**

```
> match
```

**math**

**version:** 0.61.0

**usage:**

Use mathematical functions as aggregate functions on a list of numbers or tables.

**Signature**

```
> math
```

**math abs**

**version:** 0.61.0

**usage:**

Returns absolute values of a list of numbers

**Signature**

```
> math abs
```

**Examples**

Get absolute of each value in a list of numbers

```
> [-50 -100.0 25] | math abs
```

## math avg

**version:** 0.61.0

### usage:

Finds the average of a list of numbers or tables

### Signature

```
> math avg
```

### Examples

Get the average of a list of numbers

```
> [-50 100.0 25] | math avg
```

## math ceil

**version:** 0.61.0

### usage:

Applies the ceil function to a list of numbers

### Signature

```
> math ceil
```

### Examples

Apply the ceil function to a list of numbers

```
> [1.5 2.3 -3.1] | math ceil
```

## math eval

**version:** 0.61.0

**usage:**

Evaluate a math expression into a number

**Signature**

```
> math eval (math expression)
```

**Parameters**

- `math expression`: the math expression to evaluate

**Examples**

Evaluate math in the pipeline

```
> '10 / 4' | math eval
```

**math floor**

**version:** 0.61.0

**usage:**

Applies the floor function to a list of numbers

**Signature**

```
> math floor
```

**Examples**

Apply the floor function to a list of numbers

```
> [1.5 2.3 -3.1] | math floor
```

**math max**

**version:** 0.61.0

**usage:**

Finds the maximum within a list of numbers or tables

**Signature**

```
> math max
```

**Examples**

Find the maximum of list of numbers

```
> [-50 100 25] | math max
```

**math median**

**version:** 0.61.0

**usage:**

Gets the median of a list of numbers

**Signature**

```
> math median
```

**Examples**

Get the median of a list of numbers

```
> [3 8 9 12 12 15] | math median
```

**math min**

**version:** 0.61.0

**usage:**

Finds the minimum within a list of numbers or tables

## Signature

```
> math min
```

## Examples

Get the minimum of a list of numbers

```
> [-50 100 25] | math min
```

## math mode

**version:** 0.61.0

### usage:

Gets the most frequent element(s) from a list of numbers or tables

## Signature

```
> math mode
```

## Examples

Get the mode(s) of a list of numbers

```
> [3 3 9 12 12 15] | math mode
```

## math product

**version:** 0.61.0

### usage:

Finds the product of a list of numbers or tables

## Signature

```
> math product
```

## Examples

Get the product of a list of numbers

```
> [2 3 3 4] | math product
```

## math round

**version:** 0.61.0

### usage:

Applies the round function to a list of numbers

## Signature

```
> math round --precision
```

## Parameters

- `--precision {number}`: digits of precision

## Examples

Apply the round function to a list of numbers

```
> [1.5 2.3 -3.1] | math round
```

Apply the round function with precision specified

```
> [1.555 2.333 -3.111] | math round -p 2
```

## math sqrt

**version:** 0.61.0

### usage:

Applies the square root function to a list of numbers

## Signature

```
> math sqrt
```

## Examples

Apply the square root function to a list of numbers

```
> [9 16] | math sqrt
```

## math stddev

**version:** 0.61.0

### usage:

Finds the stddev of a list of numbers or tables

## Signature

```
> math stddev --sample
```

## Parameters

- **--sample:** calculate sample standard deviation

## Examples

Get the stddev of a list of numbers

```
> [1 2 3 4 5] | math stddev
```

Get the sample stddev of a list of numbers

```
> [1 2 3 4 5] | math stddev -s
```

## math sum

**version:** 0.61.0

**usage:**

Finds the sum of a list of numbers or tables

**Signature**

```
> math sum
```

**Examples**

Sum a list of numbers

```
> [1 2 3] | math sum
```

Get the disk usage for the current directory

```
> ls | get size | math sum
```

**math variance**

**version:** 0.61.0

**usage:**

Finds the variance of a list of numbers or tables

**Signature**

```
> math variance --sample
```

**Parameters**

- **--sample:** calculate sample variance

**Examples**

Get the variance of a list of numbers

```
> echo [1 2 3 4 5] | math variance
```

Get the sample variance of a list of numbers

```
> [1 2 3 4 5] | math variance -s
```

## merge

**version:** 0.61.0

### usage:

Merge a table into an input table

## Signature

```
> merge (block)
```

## Parameters

- **block:** the block to run and merge into the table

## Examples

Merge an index column into the input table

```
> [a b c] | wrap name | merge { [1 2 3] | wrap index }
```

Merge two records

```
> {a: 1, b: 2} | merge { {c: 3} }
```

## metadata

**version:** 0.61.0

### usage:

Get the metadata for items in the stream

## Signature

```
> metadata (expression)
```

## Parameters

- **expression**: the expression you want metadata for

## Examples

Get the metadata of a variable

```
> metadata $a
```

Get the metadata of the input

```
> ls | metadata
```

## mkdir

**version:** 0.61.0

### usage:

Make directories, creates intermediary directories as required.

## Signature

```
> mkdir ...rest --show-created-paths
```

## Parameters

- **...rest**: the name(s) of the path(s) to create
- **--show-created-paths**: show the path(s) created.

## Examples

Make a directory named foo

```
> mkdir foo
```

Make multiple directories and show the paths created

```
> mkdir -s foo/bar foo2
```

## module

**version:** 0.61.0

### usage:

Define a custom module

## Signature

```
> module (module_name) (block)
```

## Parameters

- `module_name`: module name
- `block`: body of the module

## Examples

Define a custom command in a module and call it

```
> module spam { export def foo [] { "foo" } }; use spam  
foo; foo
```

Define an environment variable in a module and evaluate it

```
> module foo { export env FOO_ENV { "BAZ" } }; use foo  
FOO_ENV; $env.FOO_ENV
```

Define a custom command that participates in the environment in a module and call it

```
> module foo { export def-env bar [] { let-env FOO_BAR  
= "BAZ" } }; use foo bar; bar; $env.FOO_BAR
```

## move

**version:** 0.61.0

### usage:

Move columns before or after other columns

## Signature

```
> move ...columns --after --before
```

## Parameters

- `...columns`: the columns to move
- `--after {string}`: the column that will precede the columns moved
- `--before {string}`: the column that will be the next after the columns moved

## Examples

Move a column before the first column

```
> [[name value index]; [foo a 1] [bar b 2] [baz c 3]] |  
move index --before name
```

Move multiple columns after the last column and reorder them

```
> [[name value index]; [foo a 1] [bar b 2] [baz c 3]] |  
move value name --after index
```

Move columns of a record

```
> { name: foo, value: a, index: 1 } | move name --before  
index
```

## mv

**version:** 0.61.0

**usage:**

Move files or directories.

**Signature**

```
> mv (source) (destination) --quiet
```

**Parameters**

- **source:** the location to move files/directories from
- **destination:** the location to move files/directories to
- **--quiet:** suppress output showing files moved

**Examples**

Rename a file

```
> mv before.txt after.txt
```

Move a file into a directory

```
> mv test.txt my/subdirectory
```

Move many files into a directory

```
> mv *.txt my/subdirectory
```

**n**

**version:** 0.61.0

**usage:**

Switch to the next shell.

**Signature**

```
> n
```

## Examples

Make two directories and enter new shells for them, use **n** to jump to the next shell

```
> mkdir foo bar; enter foo; enter ../bar; n
```

Run **n** several times and note the changes of current directory

```
> n
```

## nth

**version:** 0.61.0

**usage:**

Deprecated command

## Signature

```
> nth
```

## nu-highlight

**version:** 0.61.0

**usage:**

Syntax highlight the input string.

## Signature

```
> nu-highlight
```

## Examples

Describe the type of a string

```
> 'let x = 3' | nu-highlight
```

## open

**version:** 0.61.0

### usage:

Load a file into a cell, converting to table if possible (avoid by appending '--raw').

## Signature

```
> open (filename) --raw
```

## Parameters

- **filename:** the filename to use
- **--raw:** open file as raw binary

## Examples

Open a file, with structure (based on file extension)

```
> open myfile.json
```

Open a file, as raw bytes

```
> open myfile.json --raw
```

Open a file, using the input to get filename

```
> echo 'myfile.txt' | open
```

Open a file, and decode it by the specified encoding

```
> open myfile.txt --raw | decode utf-8
```

## p

**version:** 0.61.0

### usage:

Switch to the previous shell.

### Signature

```
> p
```

### Examples

Make two directories and enter new shells for them, use **p** to jump to the previous shell

```
> mkdir foo bar; enter foo; enter ../bar; p
```

Run **p** several times and note the changes of current directory

```
> p
```

## par-each

**version:** 0.61.0

### usage:

Run a block on each element of input in parallel

### Signature

```
> par-each (block) --numbered
```

### Parameters

- **block:** the block to run
- **--numbered:** iterate with an index

## Examples

Multiplies elements in list

```
> [1 2 3] | par-each { |it| 2 * $it }
```

Iterate over each element, print the matching value and its index

```
> [1 2 3] | par-each -n { |it| if $it.item == 2 { echo  
  "$found 2 at ($it.index)!" } }
```

## parse

**version:** 0.61.0

### usage:

Parse columns from string data using a simple pattern.

## Signature

```
> parse (pattern) --regex
```

## Parameters

- **pattern:** the pattern to match. Eg) “{foo}: {bar}”
- **--regex:** use full regex syntax for patterns

## Examples

Parse a string into two named columns

```
> echo "hi there" | parse "{foo} {bar}"
```

Parse a string using regex pattern

```
> echo "hi there" | parse -r '(?P<foo>\w+) (?P<bar>\w+)
```

## path

**version:** 0.61.0

### usage:

Explore and manipulate paths.

## Signature

```
> path
```

## path basename

**version:** 0.61.0

### usage:

Get the final component of a path

## Signature

```
> path basename --columns --replace
```

## Parameters

- `--columns {table}`: Optionally operate by column path
- `--replace {string}`: Return original path with basename replaced by this string

## Examples

Get basename of a path

```
> '/home/joe/test.txt' | path basename
```

Get basename of a path by column

```
> [[name];[/home/joe]] | path basename -c [ name ]
```

Replace basename of a path

```
> '/home/joe/test.txt' | path basename -r 'spam.png'
```

## path dirname

**version:** 0.61.0

### usage:

Get the parent directory of a path

### Signature

```
> path dirname --columns --replace --num-levels
```

### Parameters

- `--columns {table}`: Optionally operate by column path
- `--replace {string}`: Return original path with dirname replaced by this string
- `--num-levels {int}`: Number of directories to walk up

### Examples

Get dirname of a path

```
> '/home/joe/code/test.txt' | path dirname
```

Get dirname of a path in a column

```
> ls ('.' | path expand) | path dirname -c [ name ]
```

Walk up two levels

```
> '/home/joe/code/test.txt' | path dirname -n 2
```

Replace the part that would be returned with a custom path

```
> '/home/joe/code/test.txt' | path dirname -n 2 -r /home/  
viking
```

## path exists

**version:** 0.61.0

### usage:

Check whether a path exists

### Signature

```
> path exists --columns
```

### Parameters

- `--columns {table}`: Optionally operate by column path

### Examples

Check if a file exists

```
> '/home/joe/todo.txt' | path exists
```

Check if a file exists in a column

```
> ls | path exists -c [ name ]
```

## path expand

**version:** 0.61.0

### usage:

Try to expand a path to its absolute form

### Signature

```
> path expand --strict --columns
```

## Parameters

- **--strict**: Throw an error if the path could not be expanded
- **--columns {table}**: Optionally operate by column path

## Examples

Expand an absolute path

```
> '/home/joe/foo/../bar' | path expand
```

Expand a path in a column

```
> ls | path expand -c [ name ]
```

Expand a relative path

```
> 'foo/../bar' | path expand
```

## path join

**version:** 0.61.0

### usage:

Join a structured path or a list of path parts.

## Signature

```
> path join (append) --columns
```

## Parameters

- **append**: Path to append to the input
- **--columns {table}**: Optionally operate by column path

## Examples

Append a filename to a path

```
> '/home/viking' | path join spam.txt
```

Append a filename to a path inside a column

```
> ls | path join spam.txt -c [ name ]
```

Join a list of parts into a path

```
> [ '/' 'home' 'viking' 'spam.txt' ] | path join
```

Join a structured path into a path

```
> [[ parent stem extension ]; [ '/home/viking' 'spam' 'txt' ] ] | path join
```

## path parse

**version:** 0.61.0

### usage:

Convert a path into structured data.

## Signature

```
> path parse --columns --extension
```

## Parameters

- `--columns {table}`: Optionally operate by column path
- `--extension {string}`: Manually supply the extension (without the dot)

## Examples

Parse a path

```
> '/home/viking/spam.txt' | path parse
```

Replace a complex extension

```
> '/home/viking/spam.tar.gz' | path parse -e tar.gz | upsert  
extension { 'txt' }
```

Ignore the extension

```
> '/etc/conf.d' | path parse -e ''
```

Parse all paths under the 'name' column

```
> ls | path parse -c [ name ]
```

## path relative-to

version: 0.61.0

### usage:

Get a path as relative to another path.

### Signature

```
> path relative-to (path) --columns
```

### Parameters

- path: Parent shared with the input path
- --columns {table}: Optionally operate by column path

### Examples

Find a relative path from two absolute paths

```
> '/home/viking' | path relative-to '/home'
```

Find a relative path from two absolute paths in a column

```
> ls ~ | path relative-to ~ -c [ name ]
```

Find a relative path from two relative paths

```
> 'eggs/bacon/sausage/spam' | path relative-to 'eggs/bacon/sausage'
```

## path split

version: 0.61.0

### usage:

Split a path into parts by a separator.

### Signature

```
> path split --columns
```

### Parameters

- `--columns {table}`: Optionally operate by column path

### Examples

Split a path into parts

```
> '/home/viking/spam.txt' | path split
```

Split all paths under the ‘name’ column

```
> ls ('.' | path expand) | path split -c [ name ]
```

## path type

version: 0.61.0

**usage:**

Get the type of the object a path refers to (e.g., file, dir, symlink)

**Signature**

```
> path type --columns
```

**Parameters**

- `--columns {table}`: Optionally operate by column path

**Examples**

Show type of a filepath

```
> '.' | path type
```

Show type of a filepath in a column

```
> ls | path type -c [ name ]
```

**pivot**

**version:** 0.61.0

**usage:**

Deprecated command

**Signature**

```
> pivot
```

**post**

**version:** 0.61.0

**usage:**

Post a body to a URL.

## Signature

```
> post (path) (body) --user --password --content-type --content-length --headers --raw --insecure
```

## Parameters

- `path`: the URL to post to
- `body`: the contents of the post body
- `--user {any}`: the username when authenticating
- `--password {any}`: the password when authenticating
- `--content-type {any}`: the MIME type of content to post
- `--content-length {any}`: the length of the content being posted
- `--headers {any}`: custom headers you want to add
- `--raw`: return values as a string instead of a table
- `--insecure`: allow insecure server connections when using SSL

## Examples

Post content to url.com

```
> post url.com 'body'
```

Post content to url.com, with username and password

```
> post -u myuser -p mypass url.com 'body'
```

Post content to url.com, with custom header

```
> post -H [my-header-key my-header-value] url.com
```

Post content to url.com with a json body

```
> post -t application/json url.com { field: value }
```

## prepend

**version:** 0.61.0

### usage:

Prepend any number of rows to a table.

### Signature

```
> prepend (row)
```

### Parameters

- **row:** the row, list, or table to prepend

### Examples

Prepend one Int item

```
> [1,2,3,4] | prepend 0
```

Prepend two Int items

```
> [2,3,4] | prepend [0,1]
```

Prepend Ints and Strings

```
> [2,nu,4,shell] | prepend [0,1,rocks]
```

## print

**version:** 0.61.0

### usage:

Prints the values given

### Signature

```
> print ...rest
```

## Parameters

- `...rest`: the values to print

## Examples

Print 'hello world'

```
> print "hello world"
```

Print the sum of 2 and 3

```
> print (2 + 3)
```

## ps

**version:** 0.61.0

### usage:

View information about system processes.

## Signature

```
> ps --long
```

## Parameters

- `--long`: list all available columns for each entry

## Examples

List the system processes

```
> ps
```

List the top 5 system processes with the highest memory usage

```
> ps | sort-by mem | last 5
```

List the top 3 system processes with the highest CPU usage

```
> ps | sort-by cpu | last 3
```

List the system processes with ‘nu’ in their names

```
> ps | where name =~ 'nu'
```

## random

**version:** 0.61.0

### usage:

Generate a random values.

## Signature

```
> random
```

## random bool

**version:** 0.61.0

### usage:

Generate a random boolean value

## Signature

```
> random bool --bias
```

## Parameters

- `--bias {number}`: Adjusts the probability of a “true” outcome

## Examples

Generate a random boolean value

```
> random bool
```

Generate a random boolean value with a 75% chance of “true”

```
> random bool --bias 0.75
```

## random chars

**version:** 0.61.0

### usage:

Generate random chars

### Signature

```
> random chars --length
```

### Parameters

- `--length {int}`: Number of chars

### Examples

Generate random chars

```
> random chars
```

Generate random chars with specified length

```
> random chars -l 20
```

## random decimal

**version:** 0.61.0

### usage:

Generate a random decimal within a range [min..max]

## Signature

```
> random decimal (range)
```

## Parameters

- range: Range of values

## Examples

Generate a default decimal value between 0 and 1

```
> random decimal
```

Generate a random decimal less than or equal to 500

```
> random decimal ..500
```

Generate a random decimal greater than or equal to 100000

```
> random decimal 100000..
```

Generate a random decimal between 1.0 and 1.1

```
> random decimal 1.0..1.1
```

## random dice

**version:** 0.61.0

### usage:

Generate a random dice roll

## Signature

```
> random dice --dice --sides
```

## Parameters

- `--dice {int}`: The amount of dice being rolled
- `--sides {int}`: The amount of sides a die has

## Examples

Roll 1 dice with 6 sides each

```
> random dice
```

Roll 10 dice with 12 sides each

```
> random dice -d 10 -s 12
```

## random integer

**version:** 0.61.0

### usage:

Generate a random integer [min..max]

## Signature

```
> random integer (range)
```

## Parameters

- **range:** Range of values

## Examples

Generate an unconstrained random integer

```
> random integer
```

Generate a random integer less than or equal to 500

```
> random integer ..500
```

Generate a random integer greater than or equal to 100000

```
> random integer 100000..
```

Generate a random integer between 1 and 10

```
> random integer 1..10
```

## random uuid

**version:** 0.61.0

### usage:

Generate a random uuid4 string

### Signature

```
> random uuid
```

## Examples

Generate a random uuid4 string

```
> random uuid
```

## range

**version:** 0.61.0

### usage:

Return only the selected rows.

### Signature

```
> range (rows)
```

## Parameters

- **rows**: range of rows to return: Eg) 4..7 (=> from 4 to 7)

## Examples

Get the last 2 items

```
> [0,1,2,3,4,5] | range 4..5
```

Get the last 2 items

```
> [0,1,2,3,4,5] | range (-2)..
```

Get the next to last 2 items

```
> [0,1,2,3,4,5] | range (-3)..-2
```

## reduce

**version:** 0.61.0

### usage:

Aggregate a list table to a single value using an accumulator block.

## Signature

```
> reduce (block) --fold --numbered
```

## Parameters

- **block**: reducing function
- **--fold {any}**: reduce with initial value
- **--numbered**: iterate with an index

## Examples

Sum values of a list (same as 'math sum')

```
> [ 1 2 3 4 ] | reduce {|it, acc| $it + $acc }
```

Sum values of a list (same as ‘math sum’)

```
> [ 1 2 3 ] | reduce -n {|it, acc| $acc + $it.item }
```

Sum values with a starting value (fold)

```
> [ 1 2 3 4 ] | reduce -f 10 {|it, acc| $acc + $it }
```

Replace selected characters in a string with ‘X’

```
> [ i o t ] | reduce -f "Arthur, King of the Britons" {|it, acc| $acc | str replace -a $it "X" }
```

Find the longest string and its index

```
> [ one longest three bar ] | reduce -n { |it, acc|
                                if ($it.item | str length) > ($acc |
str length) {
                                    $it.item
                                } else {
                                    $acc
                                }
}
```

## register

version: 0.61.0

### usage:

Register a plugin

### Signature

```
> register (plugin) (signature) --encoding --shell
```

## Parameters

- **plugin**: path of executable for plugin
- **signature**: Block with signature description as json object
- **--encoding {string}**: Encoding used to communicate with plugin. Options: [capnp, json]
- **--shell {path}**: path of shell used to run plugin (cmd, sh, python, etc)

## Examples

Register `nu_plugin_query` plugin from `~/.cargo/bin/` dir

```
> register -e json ~/.cargo/bin/nu_plugin_query
```

Register `nu_plugin_query` plugin from `nu -c`(plugin will be available in that nu session only)

```
> let plugin = ((which nu).path.0 | path dirname | path  
join 'nu_plugin_query'); nu -c '$register -e json ($plugin)  
; version'
```

## reject

**version:** 0.61.0

### usage:

Remove the given columns from the table. If you want to remove rows, try 'drop'.

## Signature

```
> reject ...rest
```

## Parameters

- **...rest**: the names of columns to remove from the table

## Examples

Lists the files in a directory without showing the modified column

```
> ls | reject modified
```

Reject the specified field in a record

```
> echo {a: 1, b: 2} | reject a
```

## rename

**version:** 0.61.0

### usage:

Creates a new table with columns renamed.

## Signature

```
> rename ...rest --column
```

## Parameters

- `...rest`: the new names for the columns
- `--column {list<string>}`: column name to be changed

## Examples

Rename a column

```
> [[a, b]; [1, 2]] | rename my_column
```

Rename many columns

```
> [[a, b, c]; [1, 2, 3]] | rename eggs ham bacon
```

Rename a specific column

```
> [[a, b, c]; [1, 2, 3]] | rename -c [a ham]
```

## reverse

**version:** 0.61.0

### usage:

Reverses the table.

## Signature

```
> reverse
```

## Examples

Reverse the items

```
> [0,1,2,3] | reverse
```

## rm

**version:** 0.61.0

### usage:

Remove file(s).

## Signature

```
> rm ...rest --trash --permanent --recursive --force --quiet
```

## Parameters

- **...rest:** the file path(s) to remove
- **--trash:** use the platform's recycle bin instead of permanently deleting
- **--permanent:** don't use recycle bin, delete permanently

- **--recursive**: delete subdirectories recursively
- **--force**: suppress error when no file
- **--quiet**: suppress output showing files deleted

## Examples

Delete or move a file to the system trash (depending on ‘rm\_always\_trash’ config option)

```
> rm file.txt
```

Move a file to the system trash

```
> rm --trash file.txt
```

Delete a file permanently

```
> rm --permanent file.txt
```

Delete a file, and suppress errors if no file is found

```
> rm --force file.txt
```

## roll

**version:** 0.61.0

### usage:

Rolling commands for tables

## Signature

```
> roll
```

## roll down

**version:** 0.61.0

**usage:**

Roll table rows down

**Signature**

```
> roll down --by
```

**Parameters**

- `--by {int}`: Number of rows to roll

**Examples**

Rolls rows down

```
> [[a b]; [1 2] [3 4] [5 6]] | roll down
```

**roll left**

**version:** 0.61.0

**usage:**

Roll table columns left

**Signature**

```
> roll left --by --cells-only
```

**Parameters**

- `--by {int}`: Number of columns to roll
- `--cells-only`: rotates columns leaving headers fixed

**Examples**

Rolls columns to the left

```
> [[a b c]; [1 2 3] [4 5 6]] | roll left
```

Rolls columns to the left with fixed headers

```
> [[a b c]; [1 2 3] [4 5 6]] | roll left --cells-only
```

## roll right

**version:** 0.61.0

### usage:

Roll table columns right

### Signature

```
> roll right --by --cells-only
```

### Parameters

- `--by {int}`: Number of columns to roll
- `--cells-only`: rotates columns leaving headers fixed

### Examples

Rolls columns to the right

```
> [[a b c]; [1 2 3] [4 5 6]] | roll right
```

Rolls columns to the right with fixed headers

```
> [[a b c]; [1 2 3] [4 5 6]] | roll right --cells-only
```

## roll up

**version:** 0.61.0

**usage:**

Roll table rows up

**Signature**

```
> roll up --by
```

**Parameters**

- `--by {int}`: Number of rows to roll

**Examples**

Rolls rows up

```
> [[a b]; [1 2] [3 4] [5 6]] | roll up
```

**rotate**

**version:** 0.61.0

**usage:**

Rotates a table clockwise (default) or counter-clockwise (use `--ccw` flag).

**Signature**

```
> rotate ...rest --ccw
```

**Parameters**

- `...rest`: the names to give columns once rotated
- `--ccw`: rotate counter clockwise

**Examples**

Rotate 2x2 table clockwise

```
> [[a b]; [1 2]] | rotate
```

Rotate 2x3 table clockwise

```
> [[a b]; [1 2] [3 4] [5 6]] | rotate
```

Rotate table clockwise and change columns names

```
> [[a b]; [1 2]] | rotate col_a col_b
```

Rotate table counter clockwise

```
> [[a b]; [1 2]] | rotate --ccw
```

Rotate table counter-clockwise

```
> [[a b]; [1 2] [3 4] [5 6]] | rotate --ccw
```

Rotate table counter-clockwise and change columns names

```
> [[a b]; [1 2]] | rotate --ccw col_a col_b
```

## run-external

version: 0.61.0

### usage:

Runs external command

### Signature

```
> run-external ...rest --redirect-stdout --redirect-stderr
```

### Parameters

- `...rest`: external command to run
- `--redirect-stdout`: redirect-stdout
- `--redirect-stderr`: redirect-stderr

## Examples

Run an external command

```
> run-external "echo" "-n" "hello"
```

## save

**version:** 0.61.0

### usage:

Save a file.

## Signature

```
> save (filename) --raw --append
```

## Parameters

- **filename:** the filename to use
- **--raw:** save file as raw binary
- **--append:** append input to the end of the file

## Examples

Save a string to foo.txt in current directory

```
> echo 'save me' | save foo.txt
```

Save a record to foo.json in current directory

```
> echo { a: 1, b: 2 } | save foo.json
```

## select

**version:** 0.61.0

**usage:**

Down-select table to only these columns.

**Signature**

```
> select ...rest
```

**Parameters**

- `...rest`: the columns to select from the table

**Examples**

Select just the name column

```
> ls | select name
```

Select the name and size columns

```
> ls | select name size
```

**seq**

**version:** 0.61.0

**usage:**

Print sequences of numbers.

**Signature**

```
> seq ...rest --separator --terminator --widths
```

**Parameters**

- `...rest`: sequence values
- `--separator {string}`: separator character (defaults to `\n`)
- `--terminator {string}`: terminator character (defaults to `\n`)
- `--widths`: equalize widths of all numbers by padding with zeros

## Examples

sequence 1 to 10 with newline separator

```
> seq 1 10
```

sequence 1.0 to 2.0 by 0.1s with newline separator

```
> seq 1.0 0.1 2.0
```

sequence 1 to 10 with pipe separator

```
> seq -s '|' 1 10
```

sequence 1 to 10 with pipe separator padded with 0

```
> seq -s '|' -w 1 10
```

sequence 1 to 10 with pipe separator padded by 2s

```
> seq -s ' | ' -w 1 2 10
```

## seq date

**version:** 0.61.0

### usage:

Print sequences of dates

## Signature

```
> seq date --separator --output-format --input-format --begin-date --end-date --increment --days --reverse
```

## Parameters

- **--separator {string}**: separator character (defaults to \n)

- `--output-format {string}`: prints dates in this format (defaults to `%Y-%m-%d`)
- `--input-format {string}`: give argument dates in this format (defaults to `%Y-%m-%d`)
- `--begin-date {string}`: beginning date range
- `--end-date {string}`: ending date
- `--increment {int}`: increment dates by this number
- `--days {int}`: number of days to print
- `--reverse`: print dates in reverse

## Examples

print the next 10 days in YYYY-MM-DD format with newline separator

```
> seq date --days 10
```

print the previous 10 days in YYYY-MM-DD format with newline separator

```
> seq date --days 10 -r
```

print the previous 10 days starting today in MM/DD/YYYY format with newline separator

```
> seq date --days 10 -o '%m/%d/%Y' -r
```

print the first 10 days in January, 2020

```
> seq date -b '2020-01-01' -e '2020-01-10'
```

print every fifth day between January 1st 2020 and January 31st 2020

```
> seq date -b '2020-01-01' -e '2020-01-31' -n 5
```

starting on May 5th, 2020, print the next 10 days in your locale's date format, colon separated

```
> seq date -o %x -s ':' -d 10 -b '2020-05-01'
```

## shells

**version:** 0.61.0

### usage:

Lists all open shells.

## Signature

```
> shells
```

## Examples

Enter a new shell at parent path `..` and show all opened shells

```
> enter ..; shells
```

Show currently active shell

```
> shells | where active == true
```

## shuffle

**version:** 0.61.0

### usage:

Shuffle rows randomly.

## Signature

```
> shuffle
```

## Examples

Shuffle rows randomly (execute it several times and see the difference)

```
> echo [[version patch]; [1.0.0 false] [3.0.1 true] [2.0.0 false]] | shuffle
```

## size

**version:** 0.61.0

### usage:

Gather word count statistics on the text.

## Signature

```
> size
```

## Examples

Count the number of words in a string

```
> "There are seven words in this sentence" | size
```

Counts unicode characters

```
> ' ' | size
```

Counts Unicode characters correctly in a string

```
> "Amélie Amelie" | size
```

## skip

**version:** 0.61.0

### usage:

Skip the first n elements of the input.

## Signature

```
> skip (n)
```

## Parameters

- **n**: the number of elements to skip

## Examples

Skip two elements

```
> echo [[editions]; [2015] [2018] [2021]] | skip 2
```

Skip the first value

```
> echo [2 4 6 8] | skip
```

## skip until

**version:** 0.61.0

### usage:

Skip elements of the input until a predicate is true.

## Signature

```
> skip until (predicate)
```

## Parameters

- **predicate**: the predicate that skipped element must not match

## Examples

Skip until the element is positive

```
> echo [-2 0 2 -1] | skip until $it > 0
```

## skip while

**version:** 0.61.0

### usage:

Skip elements of the input while a predicate is true.

### Signature

```
> skip while (predicate)
```

### Parameters

- **predicate:** the predicate that skipped element must match

### Examples

Skip while the element is negative

```
> echo [-2 0 2 -1] | skip while $it < 0
```

## sleep

**version:** 0.61.0

### usage:

Delay for a specified amount of time.

### Signature

```
> sleep (duration) ...rest
```

### Parameters

- **duration:** time to sleep
- **...rest:** additional time

## Examples

Sleep for 1sec

```
> sleep 1sec
```

Sleep for 3sec

```
> sleep 1sec 1sec 1sec
```

Send output after 1sec

```
> sleep 1sec; echo done
```

## sort

**version:** 0.61.0

### usage:

Sort by the given columns, in increasing order.

## Signature

```
> sort --reverse --insensitive
```

## Parameters

- **--reverse:** Sort in reverse order
- **--insensitive:** Sort string-based columns case-insensitively

## Examples

sort the list by increasing value

```
> [2 0 1] | sort
```

sort the list by decreasing value

```
> [2 0 1] | sort -r
```

sort a list of strings

```
> [betty amy sarah] | sort
```

sort a list of strings in reverse

```
> [betty amy sarah] | sort -r
```

Sort strings (case-insensitive)

```
> echo [airplane Truck Car] | sort -i
```

Sort strings (reversed case-insensitive)

```
> echo [airplane Truck Car] | sort -i -r
```

## sort-by

**version:** 0.61.0

### usage:

Sort by the given columns, in increasing order.

## Signature

```
> sort-by ...columns --reverse --insensitive
```

## Parameters

- **...columns:** the column(s) to sort by
- **--reverse:** Sort in reverse order
- **--insensitive:** Sort string-based columns case-insensitively

## Examples

sort the list by increasing value

```
> [2 0 1] | sort-by
```

sort the list by decreasing value

```
> [2 0 1] | sort-by -r
```

sort a list of strings

```
> [betty amy sarah] | sort-by
```

sort a list of strings in reverse

```
> [betty amy sarah] | sort-by -r
```

Sort strings (case-insensitive)

```
> echo [airplane Truck Car] | sort-by -i
```

Sort strings (reversed case-insensitive)

```
> echo [airplane Truck Car] | sort-by -i -r
```

Sort a table by its column (reversed order)

```
> [[fruit count]; [apple 9] [pear 3] [orange 7]] | sort-  
by fruit -r
```

## source

**version:** 0.61.0

### usage:

Runs a script file in the current context.

## Signature

```
> source (filename)
```

## Parameters

- **filename**: the filepath to the script file to source

## Examples

Runs foo.nu in the current context

```
> source foo.nu
```

Runs foo.nu in current context and call the command defined, suppose foo.nu has content: `def say-hi [] { echo 'Hi!' }`

```
> source ./foo.nu; say-hi
```

Runs foo.nu in current context and call the `main` command automatically, suppose foo.nu has content: `def main [] { echo 'Hi!' }`

```
> source ./foo.nu
```

## split-by

**version:** 0.61.0

### usage:

Create a new table splitted.

## Signature

```
> split-by (splitter)
```

## Parameters

- **splitter**: the splitter value to use

## Examples

split items by column named “lang”

```
>
      {
        '2019': [
          { name: 'andres', lang: 'rb', year:
'2019' },
          { name: 'jt', lang: 'rs', year: '2019'
}
        ],
        '2021': [
          { name: 'storm', lang: 'rs', 'year':
'2021' }
        ]
      } | split-by lang
```

## split

**version:** 0.61.0

### usage:

Split contents across desired subcommand (like row, column) via the separator.

## Signature

```
> split
```

## split chars

**version:** 0.61.0

### usage:

Split a string’s characters into separate rows

## Signature

```
> split chars
```

## Examples

Split the string's characters into separate rows

```
> 'hello' | split chars
```

## split column

version: 0.61.0

### usage:

Split a string into multiple columns using a separator

## Signature

```
> split column (separator) ...rest --collapse-empty
```

## Parameters

- **separator**: the character or string that denotes what separates columns
- **...rest**: column names to give the new columns
- **--collapse-empty**: remove empty columns

## Examples

Split a string into columns by the specified separator

```
> echo 'a--b--c' | split column '--'
```

Split a string into columns of char and remove the empty columns

```
> echo 'abc' | split column -c ''
```

## split row

**version:** 0.61.0

### usage:

Split a string into multiple rows using a separator

### Signature

```
> split row (separator)
```

### Parameters

- **separator:** the character that denotes what separates rows

### Examples

Split a string into rows of char

```
> echo 'abc' | split row ''
```

Split a string into rows by the specified separator

```
> echo 'a--b--c' | split row '--'
```

## str

**version:** 0.61.0

### usage:

Various commands for working with string data.

### Signature

```
> str
```

## str camel-case

**version:** 0.61.0

**usage:**

Convert a string to camelCase

**Signature**

```
> str camel-case ...rest
```

**Parameters**

- `...rest`: optionally convert text to camelCase by column paths

**Examples**

convert a string to camelCase

```
> 'NuShell' | str camel-case
```

convert a string to camelCase

```
> 'this-is-the-first-case' | str camel-case
```

convert a string to camelCase

```
> 'this_is_the_second_case' | str camel-case
```

convert a column from a table to camelCase

```
> [[lang, gems]; [nu_test, 100]] | str camel-case lang
```

**str capitalize**

**version:** 0.61.0

**usage:**

Capitalize text

**Signature**

```
> str capitalize ...rest
```

## Parameters

- `...rest`: optionally capitalize text by column paths

## Examples

Capitalize contents

```
> 'good day' | str capitalize
```

Capitalize contents

```
> 'anton' | str capitalize
```

Capitalize a column in a table

```
> [[lang, gems]; [nu_test, 100]] | str capitalize lang
```

## str collect

**version:** 0.61.0

### usage:

Concatenate multiple strings into a single string, with an optional separator between each

## Signature

```
> str collect (separator)
```

## Parameters

- `separator`: optional separator to use when creating string

## Examples

Create a string from input

```
> ['nu', 'shell'] | str collect
```

Create a string from input with a separator

```
> ['nu', 'shell'] | str collect '-'
```

## str contains

**version:** 0.61.0

### usage:

Checks if string contains pattern

## Signature

```
> str contains (pattern) ...rest --insensitive --not
```

## Parameters

- **pattern:** the pattern to find
- **...rest:** optionally check if string contains pattern by column paths
- **--insensitive:** search is case insensitive
- **--not:** does not contain

## Examples

Check if string contains pattern

```
> 'my_library.rb' | str contains '.rb'
```

Check if string contains pattern case insensitive

```
> 'my_library.rb' | str contains -i '.RB'
```

Check if string contains pattern in a table

```
> [[ColA ColB]; [test 100]] | str contains 'e' ColA
```

Check if string contains pattern in a table

```
> [[ColA ColB]; [test 100]] | str contains -i 'E' ColA
```

Check if string contains pattern in a table

```
> [[ColA ColB]; [test hello]] | str contains 'e' ColA  
ColB
```

Check if string contains pattern

```
> 'hello' | str contains 'banana'
```

Check if list contains pattern

```
> [one two three] | str contains o
```

Check if list does not contain pattern

```
> [one two three] | str contains -n o
```

## str downcase

**version:** 0.61.0

**usage:**

Make text lowercase

### Signature

```
> str downcase ...rest
```

### Parameters

- `...rest`: optionally downcase text by column paths

## Examples

Downcase contents

```
> 'NU' | str downcase
```

Downcase contents

```
> 'TESTa' | str downcase
```

Downcase contents

```
> [[ColA ColB]; [Test ABC]] | str downcase ColA
```

Downcase contents

```
> [[ColA ColB]; [Test ABC]] | str downcase ColA ColB
```

## str ends-with

**version:** 0.61.0

### usage:

Check if a string ends with a pattern

## Signature

```
> str ends-with (pattern) ...rest
```

## Parameters

- **pattern:** the pattern to match
- **...rest:** optionally matches suffix of text by column paths

## Examples

Checks if string ends with 'rb' pattern

```
> 'my_library.rb' | str ends-with '.rb'
```

Checks if string ends with 'txt' pattern

```
> 'my_library.rb' | str ends-with '.txt'
```

## str find-replace

**version:** 0.61.0

**usage:**

Deprecated command

### Signature

```
> str find-replace
```

## str index-of

**version:** 0.61.0

**usage:**

Returns starting index of given pattern in string counting from 0. Returns -1 when there are no results.

### Signature

```
> str index-of (pattern) ...rest --range --end
```

### Parameters

- **pattern:** the pattern to find index of
- **...rest:** optionally returns index of pattern in string by column paths
- **--range {any}:** optional start and/or end index
- **--end:** search from the end of the string

## Examples

Returns index of pattern in string

```
> 'my_library.rb' | str index-of '.rb'
```

Returns index of pattern in string with start index

```
> '.rb.rb' | str index-of '.rb' -r '1,'
```

Returns index of pattern in string with end index

```
> '123456' | str index-of '6' -r ',4'
```

Returns index of pattern in string with start and end index

```
> '123456' | str index-of '3' -r '1,4'
```

Alternatively you can use this form

```
> '123456' | str index-of '3' -r [1 4]
```

Returns index of pattern in string

```
> '/this/is/some/path/file.txt' | str index-of '/' -e
```

## str kebab-case

**version:** 0.61.0

**usage:**

Convert a string to kebab-case

## Signature

```
> str kebab-case ...rest
```

## Parameters

- `...rest`: optionally convert text to kebab-case by column paths

## Examples

convert a string to kebab-case

```
> 'NuShell' | str kebab-case
```

convert a string to kebab-case

```
> 'thisIsTheFirstCase' | str kebab-case
```

convert a string to kebab-case

```
> 'THIS_IS_THE_SECOND_CASE' | str kebab-case
```

convert a column from a table to kebab-case

```
> [[lang, gems]; [nuTest, 100]] | str kebab-case lang
```

## str length

**version:** 0.61.0

### usage:

Output the length of any strings in the pipeline

## Signature

```
> str length ...rest
```

## Parameters

- `...rest`: optionally find length of text by column paths

## Examples

Return the lengths of multiple strings

```
> 'hello' | str length
```

Return the lengths of multiple strings

```
> ['hi' 'there'] | str length
```

## str lpad

version: 0.61.0

### usage:

Left-pad a string to a specific length

## Signature

```
> str lpad ...rest --length --character
```

## Parameters

- `...rest`: optionally check if string contains pattern by column paths
- `--length {int}`: length to pad to
- `--character {string}`: character to pad with

## Examples

Left-pad a string with asterisks until it's 10 characters wide

```
> 'nushell' | str lpad -l 10 -c '*'
```

Left-pad a string with zeroes until it's 10 character wide

```
> '123' | str lpad -l 10 -c '0'
```

Use lpad to truncate a string

```
> '123456789' | str lpad -l 3 -c '0'
```

Use lpad to pad Unicode

```
> ' ' | str lpad -l 10 -c ' '
```

## str pascal-case

**version:** 0.61.0

### usage:

Convert a string to PascalCase

## Signature

```
> str pascal-case ...rest
```

## Parameters

- `...rest`: optionally convert text to PascalCase by column paths

## Examples

convert a string to PascalCase

```
> 'nu-shell' | str pascal-case
```

convert a string to PascalCase

```
> 'this-is-the-first-case' | str pascal-case
```

convert a string to PascalCase

```
> 'this_is_the_second_case' | str pascal-case
```

convert a column from a table to PascalCase

```
> [[lang, gems]; [nu_test, 100]] | str pascal-case lang
```

## str replace

**version:** 0.61.0

### usage:

Find and replace text

### Signature

```
> str replace (find) (replace) ...rest --all --no-expand --string
```

### Parameters

- **find:** the pattern to find
- **replace:** the replacement pattern
- **...rest:** optionally find and replace text by column paths
- **--all:** replace all occurrences of find string
- **--no-expand:** do not expand the replace parameter as a regular expression
- **--string:** do not use regular expressions for string find and replace

### Examples

Find and replace contents with capture group

```
> 'my_library.rb' | str replace '(.+).rb' '$1.nu'
```

Find and replace all occurrences of find string

```
> 'abc abc abc' | str replace -a 'b' 'z'
```

Find and replace all occurrences of find string in table

```
> [[ColA ColB ColC]; [abc abc ads]] | str replace -a 'b'  
'z' ColA ColC
```

Find and replace contents without using the replace parameter as a regular expression

```
> 'dogs_$1_cats' | str replace '\$1' '$2' -n
```

Find and replace the first occurrence using string replacement *not* regular expressions

```
> 'c:\some\cool\path' | str replace 'c:\some\cool' '~'  
-s
```

Find and replace all occurrences using string replacement *not* regular expressions

```
> 'abc abc abc' | str replace -a 'b' 'z' -s
```

## str reverse

version: 0.61.0

### usage:

Reverse every string in the pipeline

### Signature

```
> str reverse ...rest
```

### Parameters

- `...rest`: optionally reverse text by column paths

## Examples

Reverse a single string

```
> 'Nushell' | str reverse
```

Reverse multiple strings in a list

```
> ['Nushell' 'is' 'cool'] | str reverse
```

## str rpad

version: 0.61.0

### usage:

Right-pad a string to a specific length

## Signature

```
> str rpad ...rest --length --character
```

## Parameters

- `...rest`: optionally check if string contains pattern by column paths
- `--length {int}`: length to pad to
- `--character {string}`: character to pad with

## Examples

Right-pad a string with asterisks until it's 10 characters wide

```
> 'nushell' | str rpad -l 10 -c '*'
```

Right-pad a string with zeroes until it's 10 characters wide

```
> '123' | str rpad -l 10 -c '0'
```

Use rpad to truncate a string

```
> '123456789' | str rpad -l 3 -c '0'
```

Use rpad to pad Unicode

```
> ' ' | str rpad -l 10 -c ' '
```

## str screaming-snake-case

**version:** 0.61.0

### usage:

Convert a string to SCREAMING\_SNAKE\_CASE

### Signature

```
> str screaming-snake-case ...rest
```

### Parameters

- **...rest:** optionally convert text to SCREAMING\_SNAKE\_CASE by column paths

### Examples

convert a string to camelCase

```
> "NuShell" | str screaming-snake-case
```

convert a string to camelCase

```
> "this_is_the_second_case" | str screaming-snake-case
```

convert a string to camelCase

```
> "this-is-the-first-case" | str screaming-snake-case
```

convert a column from a table to SCREAMING\_SNAKE\_CASE

```
> [[lang, gems]; [nu_test, 100]] | str screaming-snake-  
case lang
```

## str snake-case

**version:** 0.61.0

### usage:

Convert a string to snake\_case

### Signature

```
> str snake-case ...rest
```

### Parameters

- `...rest`: optionally convert text to snake\_case by column paths

### Examples

convert a string to camelCase

```
> "NuShell" | str snake-case
```

convert a string to camelCase

```
> "this_is_the_second_case" | str snake-case
```

convert a string to camelCase

```
> "this-is-the-first-case" | str snake-case
```

convert a column from a table to snake-case

```
> [[lang, gems]; [nuTest, 100]] | str snake-case lang
```

## str starts-with

version: 0.61.0

### usage:

Check if string starts with a pattern

### Signature

```
> str starts-with (pattern) ...rest
```

### Parameters

- **pattern**: the pattern to match
- **...rest**: optionally matches prefix of text by column paths

### Examples

Checks if string starts with ‘my’ pattern

```
> 'my_library.rb' | str starts-with 'my'
```

Checks if string starts with ‘my’ pattern

```
> 'Cargo.toml' | str starts-with 'Car'
```

Checks if string starts with ‘my’ pattern

```
> 'Cargo.toml' | str starts-with '.toml'
```

## str substring

version: 0.61.0

**usage:**

Get part of a string

**Signature**

```
> str substring (range) ...rest
```

**Parameters**

- **range**: the indexes to substring [start end]
- **...rest**: optionally substring text by column paths

**Examples**

Get a substring from the text

```
> 'good nushell' | str substring [5 12]
```

Alternatively, you can use the form

```
> 'good nushell' | str substring '5,12'
```

Drop the last **n** characters from the string

```
> 'good nushell' | str substring ',-5'
```

Get the remaining characters from a starting index

```
> 'good nushell' | str substring '5,'
```

Get the characters from the beginning until ending index

```
> 'good nushell' | str substring ',7'
```

**str to-datetime**

**version:** 0.61.0

**usage:**

Deprecated command

**Signature**

```
> str to-datetime
```

**str to-decimal**

**version:** 0.61.0

**usage:**

Deprecated command

**Signature**

```
> str to-decimal
```

**str to-int**

**version:** 0.61.0

**usage:**

Deprecated command

**Signature**

```
> str to-int
```

**str trim**

**version:** 0.61.0

**usage:**

Trim whitespace or specific character

## Signature

```
> str trim ...rest --char --left --right --all --both --format
```

## Parameters

- `...rest`: optionally trim text by column paths
- `--char {string}`: character to trim (default: whitespace)
- `--left`: trims characters only from the beginning of the string (default: whitespace)
- `--right`: trims characters only from the end of the string (default: whitespace)
- `--all`: trims all characters from both sides of the string *and* in the middle (default: whitespace)
- `--both`: trims all characters from left and right side of the string (default: whitespace)
- `--format`: trims spaces replacing multiple characters with singles in the middle (default: whitespace)

## Examples

Trim whitespace

```
> 'Nu shell ' | str trim
```

Trim a specific character

```
> '=== Nu shell ===' | str trim -c '=' | str trim
```

Trim all characters

```
> ' Nu shell ' | str trim -a
```

Trim whitespace from the beginning of string

```
> ' Nu shell ' | str trim -l
```

Trim a specific character

```
> '=== Nu shell ===' | str trim -c '='
```

Trim whitespace from the end of string

```
> ' Nu shell ' | str trim -r
```

Trim a specific character

```
> '=== Nu shell ===' | str trim -r -c '='
```

## str upcase

**version:** 0.61.0

### usage:

Make text uppercase

### Signature

```
> str upcase ...rest
```

### Parameters

- `...rest`: optionally upcase text by column paths

### Examples

Uppcase contents

```
> 'nu' | str upcase
```

## sys

**version:** 0.61.0

**usage:**

View information about the system.

**Signature**

```
> sys
```

**Examples**

Show info about the system

```
> sys
```

Show the os system name with get

```
> (sys).host | get name
```

Show the os system name

```
> (sys).host.name
```

**table**

**version:** 0.61.0

**usage:**

Render the table.

**Signature**

```
> table --start-number
```

**Parameters**

- `--start-number {int}`: row number to start viewing from

## Examples

List the files in current directory with index number start from 1.

```
> ls | table -n 1
```

Render data in table view

```
> echo [[a b]; [1 2] [3 4]] | table
```

## term size

**version:** 0.61.0

### usage:

Returns the terminal size

## Signature

```
> term size --columns --rows
```

## Parameters

- **--columns:** Report only the width of the terminal
- **--rows:** Report only the height of the terminal

## Examples

Return the width height of the terminal

```
> term size
```

Return the width (columns) of the terminal

```
> term size -c
```

Return the height (rows) of the terminal

```
> term size -r
```

## to

**version:** 0.61.0

### usage:

Translate structured data to a format

## Signature

```
> to
```

## to csv

**version:** 0.61.0

### usage:

Convert table into .csv text

## Signature

```
> to csv --separator --noheaders
```

## Parameters

- **--separator {string}**: a character to separate columns, defaults to ','
- **--noheaders**: do not output the columns names as the first row

## Examples

Outputs an CSV string representing the contents of this table

```
> [[foo bar]; [1 2]] | to csv
```

Outputs an CSV string representing the contents of this table

```
> [[foo bar]; [1 2]] | to csv -s ';' 
```

## to html

**version:** 0.61.0

### usage:

Convert table into simple HTML

## Signature

```
> to html --html-color --no-color --dark --partial --theme -  
-list
```

## Parameters

- **--html-color:** change ansi colors to html colors
- **--no-color:** remove all ansi colors in output
- **--dark:** indicate your background color is a darker color
- **--partial:** only output the html for the content itself
- **--theme {string}:** the name of the theme to use (github, blu-locolight, ...)
- **--list:** list the names of all available themes

## Examples

Outputs an HTML string representing the contents of this table

```
> [[foo bar]; [1 2]] | to html
```

Optionally, only output the html for the content itself

```
> [[foo bar]; [1 2]] | to html --partial
```

Optionally, output the string with a dark background

```
> [[foo bar]; [1 2]] | to html --dark
```

## to json

**version:** 0.61.0

### usage:

Converts table data into JSON text.

## Signature

```
> to json --raw --indent --tabs
```

## Parameters

- **--raw:** remove all of the whitespace
- **--indent {number}:** specify indentation width
- **--tabs {number}:** specify indentation tab quantity

## Examples

Outputs a JSON string, with default indentation, representing the contents of this table

```
> [a b c] | to json
```

Outputs a JSON string, with 4-space indentation, representing the contents of this table

```
> [Joe Bob Sam] | to json -i 4
```

Outputs an unformatted JSON string representing the contents of this table

```
> [1 2 3] | to json -r
```

## to md

**version:** 0.61.0

### usage:

Convert table into simple Markdown

## Signature

```
> to md --pretty --per-element
```

## Parameters

- **--pretty:** Formats the Markdown table to vertically align items
- **--per-element:** treat each row as markdown syntax element

## Examples

Outputs an MD string representing the contents of this table

```
> [[foo bar]; [1 2]] | to md
```

Optionally, output a formatted markdown string

```
> [[foo bar]; [1 2]] | to md --pretty
```

Treat each row as a markdown element

```
> [{"H1": "Welcome to Nushell"}] | [[foo bar]; [1 2]] |  
to md --per-element --pretty
```

## to nuon

**version:** 0.61.0

### usage:

Converts table data into Nuon (Nushell Object Notation) text.

## Signature

```
> to nuon
```

## Examples

Outputs a nuon string representing the contents of this table

```
> [1 2 3] | to nuon
```

## to toml

**version:** 0.61.0

### usage:

Convert table into .toml text

## Signature

```
> to toml
```

## Examples

Outputs an TOML string representing the contents of this table

```
> [[foo bar]; ["1" "2"]] | to toml
```

## to tsv

**version:** 0.61.0

### usage:

Convert table into .tsv text

## Signature

```
> to tsv --noheaders
```

## Parameters

- `--noheaders`: do not output the column names as the first row

## Examples

Outputs an TSV string representing the contents of this table

```
> [[foo bar]; [1 2]] | to tsv
```

## to url

**version:** 0.61.0

### usage:

Convert table into url-encoded text

## Signature

```
> to url
```

## Examples

Outputs an URL string representing the contents of this table

```
> [[foo bar]; ["1" "2"]] | to url
```

## to xml

**version:** 0.61.0

### usage:

Convert table into .xml text

## Signature

```
> to xml --pretty
```

## Parameters

- `--pretty {int}`: Formats the XML text with the provided indentation setting

## Examples

Outputs an XML string representing the contents of this table

```
> { "note": { "children": [{ "remember": {"attributes"
: {}, "children": [Event]}}], "attributes": {} } } | to
xml
```

Optionally, formats the text with a custom indentation setting

```
> { "note": { "children": [{ "remember": {"attributes"
: {}, "children": [Event]}}], "attributes": {} } } | to
xml -p 3
```

## to yaml

**version:** 0.61.0

### usage:

Convert table into .yaml/.yml text

## Signature

```
> to yaml
```

## Examples

Outputs an YAML string representing the contents of this table

```
> [[foo bar]; ["1" "2"]] | to yaml
```

## touch

**version:** 0.61.0

## usage:

Creates one or more files.

## Signature

```
> touch (filename) ...rest --timestamp --date --reference --modified --access --no-create
```

## Parameters

- **filename**: the path of the file you want to create
- **...rest**: additional files to create
- **--timestamp {string}**: change the file or directory time to a timestamp. Format: [[CC]YY]MMDDhhmm[.ss]  
If neither YY or CC is given, the current year will be assumed. If YY is specified, but CC is not, CC will be derived as follows: If YY is between [69, 99], CC is 19 If YY is between [00, 68], CC is 20 Note: It is expected that in a future version of this standard the default century inferred from a 2-digit year will change
- **--date {string}**: change the file or directory time to a date
- **--reference {string}**: change the file or directory time to the time of the reference file/directory
- **--modified**: change the modification time of the file or directory. If no timestamp, date or reference file/directory is given, the current time is used
- **--access**: change the access time of the file or directory. If no timestamp, date or reference file/directory is given, the current time is used
- **--no-create**: do not create the file if it does not exist

## Examples

Creates “fixture.json”

```
> touch fixture.json
```

Creates files a, b and c

```
> touch a b c
```

Changes the last modified time of “fixture.json” to today’s date

```
> touch -m fixture.json
```

Creates files d and e and set its last modified time to a timestamp

```
> touch -m -t 201908241230.30 d e
```

Changes the last modified time of files a, b and c to a date

```
> touch -m -d "yesterday" a b c
```

Changes the last modified time of file d and e to “fixture.json”’s last modified time

```
> touch -m -r fixture.json d e
```

Changes the last accessed time of “fixture.json” to a date

```
> touch -a -d "August 24, 2019; 12:30:30" fixture.json
```

Changes both last modified and accessed time of a, b and c to a timestamp only if they exist

```
> touch -c -t 201908241230.30 a b c
```

## transpose

**version:** 0.61.0

### usage:

Transposes the table contents so rows become columns and columns become rows.

## Signature

```
> transpose ...rest --header-row --ignore-titles
```

## Parameters

- `...rest`: the names to give columns once transposed
- `--header-row`: treat the first row as column names
- `--ignore-titles`: don't transpose the column names into values

## Examples

Transposes the table contents with default column names

```
> echo [[c1 c2]; [1 2]] | transpose
```

Transposes the table contents with specified column names

```
> echo [[c1 c2]; [1 2]] | transpose key val
```

Transposes the table without column names and specify a new column name

```
> echo [[c1 c2]; [1 2]] | transpose -i val
```

## tutor

version: 0.61.0

### usage:

Run the tutorial. To begin, run: tutor

## Signature

```
> tutor (search) --find
```

## Parameters

- **search**: item to search for, or 'list' to list available tutorials
- **--find {string}**: Search tutorial for a phrase

## Examples

Begin the tutorial

```
> tutor begin
```

Search a tutorial by phrase

```
> tutor -f "$in"
```

## unalias

**version:** 0.61.0

**usage:**

Deprecated command

## Signature

```
> unalias
```

## uniq

**version:** 0.61.0

**usage:**

Return the unique rows.

## Signature

```
> uniq --count --repeated --ignore-case --unique
```

## Parameters

- **--count**: Count the unique rows
- **--repeated**: Count the rows that has more than one value
- **--ignore-case**: Ignore differences in case when comparing
- **--unique**: Only return unique values

## Examples

Remove duplicate rows of a list/table

```
> [2 3 3 4] | uniq
```

Only print duplicate lines, one for each group

```
> [1 2 2] | uniq -d
```

Only print unique lines

```
> [1 2 2] | uniq -u
```

Ignore differences in case when comparing

```
> ['hello' 'goodbye' 'Hello'] | uniq -i
```

Remove duplicate rows and show counts of a list/table

```
> [1 2 2] | uniq -c
```

## update

**version:** 0.61.0

### usage:

Update an existing column to have a new value.

## Signature

```
> update (field) (replacement value)
```

## Parameters

- `field`: the name of the column to update
- `replacement value`: the new value to give the cell(s)

## Examples

Update a column value

```
> echo {'name': 'nu', 'stars': 5} | update name 'Nushell'
```

Use in block form for more involved updating logic

```
> echo [[count fruit]; [1 'apple']] | update count {|f|  
$f.count + 1}
```

## update cells

**version:** 0.61.0

### **usage:**

Update the table cells.

## Signature

```
> update cells (block) --columns
```

## Parameters

- `block`: the block to run an update for each cell
- `--columns {table}`: list of columns to update

## Examples

Update the zero value cells to empty strings.

```
> [
  ["2021-04-16", "2021-06-10", "2021-09-18", "2021-10-15",
   "2021-11-16", "2021-11-17", "2021-11-18"];
  [
    37,      0,      0,
    0,      37,      0,
  ] | update cells { |value|
    if $value == 0 {
      ""
    } else {
      $value
    }
  }
```

Update the zero value cells to empty strings in 2 last columns.

```
> [
  ["2021-04-16", "2021-06-10", "2021-09-18", "2021-10-15",
   "2021-11-16", "2021-11-17", "2021-11-18"];
  [
    37,      0,      0,
    0,      37,      0,
  ] | update cells -c ["2021-11-18", "2021-11-17"] { |value|
    if $value == 0 {
      ""
    } else {
      $value
    }
  }
```

## upsert

**version:** 0.61.0

### usage:

Update an existing column to have a new value, or insert a new column.

## Signature

```
> upsert (field) (replacement value)
```

## Parameters

- `field`: the name of the column to update or insert
- `replacement value`: the new value to give the cell(s)

## Examples

Update a column value

```
> echo {'name': 'nu', 'stars': 5} | upsert name 'Nushell'
```

Insert a new column

```
> echo {'name': 'nu', 'stars': 5} | upsert language 'Rust'
```

Use in block form for more involved updating logic

```
> echo [[count fruit]; [1 'apple']] | upsert count {|f|  
$f.count + 1}
```

Use in block form for more involved updating logic

```
> echo [[project, authors]; ['nu', ['Andrés', 'JT', 'Yehuda']]]  
| upsert authors {|a| $a.authors | str collect ','}
```

## url

**version:** 0.61.0

### usage:

Apply url function.

## Signature

```
> url
```

## url host

version: 0.61.0

### usage:

Get the host of a URL

### Signature

```
> url host ...rest
```

### Parameters

- ...rest: optionally operate by cell path

### Examples

Get host of a url

```
> echo 'http://www.example.com/foo/bar' | url host
```

## url path

version: 0.61.0

### usage:

Get the path of a URL

### Signature

```
> url path ...rest
```

### Parameters

- ...rest: optionally operate by cell path

## Examples

Get path of a url

```
> echo 'http://www.example.com/foo/bar' | url path
```

A trailing slash will be reflected in the path

```
> echo 'http://www.example.com/' | url path
```

## url query

**version:** 0.61.0

### usage:

Get the query string of a URL

## Signature

```
> url query ...rest
```

## Parameters

- `...rest`: optionally operate by cell path

## Examples

Get a query string

```
> echo 'http://www.example.com/?foo=bar&baz=quux' | url  
query
```

Returns an empty string if there is no query string

```
> echo 'http://www.example.com/' | url query
```

## url scheme

**version:** 0.61.0

**usage:**

Get the scheme (e.g. http, file) of a URL

**Signature**

```
> url scheme ...rest
```

**Parameters**

- `...rest`: optionally operate by cell path

**Examples**

Get the scheme of a URL

```
> echo 'http://www.example.com' | url scheme
```

You get an empty string if there is no scheme

```
> echo 'test' | url scheme
```

**use**

**version:** 0.61.0

**usage:**

Use definitions from a module

**Signature**

```
> use (pattern)
```

**Parameters**

- `pattern`: import pattern

## Examples

Define a custom command in a module and call it

```
> module spam { export def foo [] { "foo" } }; use spam  
foo; foo
```

Define an environment variable in a module and evaluate it

```
> module foo { export env FOO_ENV { "BAZ" } }; use foo  
FOO_ENV; $env.FOO_ENV
```

Define a custom command that participates in the environment in a module and call it

```
> module foo { export def-env bar [] { let-env FOO_BAR  
= "BAZ" } }; use foo bar; bar; $env.FOO_BAR
```

## version

**version:** 0.61.0

### usage:

Display Nu version.

## Signature

```
> version
```

## Examples

Display Nu version

```
> version
```

## view-source

**version:** 0.61.0

**usage:**

View a block, module, or a definition

**Signature**

```
> view-source (item)
```

**Parameters**

- `item`: name or block to view

**Examples**

View the source of a code block

```
> let abc = { echo 'hi' }; view-source $abc
```

View the source of a custom command

```
> def hi [] { echo 'Hi!' }; view-source hi
```

View the source of a custom command, which participates in the caller environment

```
> def-env foo [] { let-env BAR = 'BAZ' }; view-source foo
```

View the source of a module

```
> module mod-foo { export env FOO_ENV { 'BAZ' } }; view-source mod-foo
```

**where**

**version:** 0.61.0

**usage:**

Filter values based on a condition.

## Signature

```
> where (cond)
```

## Parameters

- `cond`: condition

## Examples

List all files in the current directory with sizes greater than 2kb

```
> ls | where size > 2kb
```

List only the files in the current directory

```
> ls | where type == file
```

List all files with names that contain “Car”

```
> ls | where name =~ "Car"
```

List all files that were modified in the last two weeks

```
> ls | where modified >= (date now) - 2wk
```

## which

**version:** 0.61.0

### usage:

Finds a program file, alias or custom command.

## Signature

```
> which (application) ...rest --all
```

## Parameters

- **application**: application
- **...rest**: additional applications
- **--all**: list all executables

## Examples

Find if the ‘myapp’ application is available

```
> which myapp
```

## window

**version**: 0.61.0

### usage:

Creates a sliding window of **window\_size** that slide by n rows/elements across input.

## Signature

```
> window (window_size) --stride
```

## Parameters

- **window\_size**: the size of each window
- **--stride {int}**: the number of rows to slide over between windows

## Examples

A sliding window of two elements

```
> echo [1 2 3 4] | window 2
```

A sliding window of two elements, with a stride of 3

```
> [1, 2, 3, 4, 5, 6, 7, 8] | window 2 --stride 3
```

## with-env

**version:** 0.61.0

### usage:

Runs a block with an environment variable set.

### Signature

```
> with-env (variable) (block)
```

### Parameters

- **variable:** the environment variable to temporarily set
- **block:** the block to run once the variable is set

### Examples

Set the MYENV environment variable

```
> with-env [MYENV "my env value"] { $env.MYENV }
```

Set by primitive value list

```
> with-env [X Y W Z] { $env.X }
```

Set by single row table

```
> with-env [[X W]; [Y Z]] { $env.W }
```

Set by row(e.g. open x.json or from json)

```
> echo '{"X":"Y","W":"Z"}' | from json | with-env $in { echo  
$env.X $env.W }
```

## wrap

**version:** 0.61.0

### usage:

Wrap the value into a column.

### Signature

```
> wrap (name)
```

### Parameters

- **name:** the name of the column

### Examples

Wrap a list into a table with a given column name

```
> echo [1 2 3] | wrap num
```

## zip

**version:** 0.61.0

### usage:

Combine a stream with the input

### Signature

```
> zip (other)
```

### Parameters

- **other:** the other input

## Examples

Zip multiple streams and get one of the results

```
> 1..3 | zip 4..6
```
